Table I shows the composition of some essential oils extracted from seeds or plants in Cyprus, as well as of the cake, according to the analyses of the Imperial Institute. Aniseed (*Pimpinella Anisum*), of which 1 000 to 2 000 cwt. are exported annually, was sold at London before the war at 27s. 6d. per cwt. The seeds yielded 2.8 % of essential oil. The cake contains neither alkaloids nor cyanogenetic glucosides, and may be used as a cattle-food. Coriander seeds (*Coriandrum sativum*) gave, by steam distillation, 0.48 % of essential oil, white cumin seeds (*Cuminum Cyminum*) 3.4 % of oil containing about 50 % of aldehydes, and black cumin seeds (*Nigella sativa*) 0.3 %. The cake of the first species contains no alkaloids or cyanogenetic glucosides, that of the last two contains a trace of alkaloid, so that their use is not advisable unless trials are previously made. The essential oil of black cumin seeds has no commercial value because of its disagreeable odour. The fixed oil, extracted with solvents (44.8 % of the seeds is estimated to be anhydrous) is brown and has a pronounced flavour and odour, so that its use as an oil-seed is only advisable when there is a scarcity of other oil-seeds. Its properties are:— specific gravity 0.8614, solidifying point of fatty acids 22.3° C., acid value 101.2, saponification value 198.0, iodine value 123.8 %, unsaponifiable matter 0.9 %.

The ordinary organum oil produced in Cyprus is obtained by the distillation of *Origanum dubium*. In 1913 a new form, locally known as "rik-

(1) See R. Jan., 1918, No. 5. — (2) See also R. April, 1918, No. 376. (Ed.).

hanon" was found near Lapithos and subsequently described by HOLMES as a new species under the name of *O. Bevanii*. Dried plants in flower (without the roots) yielded 1.9 % of essential oil, i. e., about half that obtained from ordinary origanum. This oil contains about 75 % of phenols which, instead of containing only one carvacrol, as those of *O. dubium*, consist of a mixture of approximately 41 parts of carvacrol and 34 of thymol.

Kyko oats from Cyprus were cultivated at Kew, where they were identified as *Avena sativa* var. *obtusata* Alef. They are commonly cultivated in South-Eastern Europe as well as in France, where they are known as Avoine blanche de Hongrie, de Pavolie, de Turquie, or de Russie. At Kew they reached a height of from 5 to 6 ft. without the roots but including the heads which were about 1 ft. long. The analyses given in Table II were made from plants in flower. The composition of white cumin chaff shows it be of great food value.

Squill (*Urginea Scilla* = *Scilla maritima*) is fairly common in Cyprus, but is not utilised. Dried slices of the bulb sent to the Imperial Institute were declared to be unsaleable because of their brown colour as the British and United States Pharmacopœias only accept yellowish-white bulbs. There are two varieties of squill, one with white bulbs, the other with red bulbs (the Cyprus squill belongs to the latter variety); both are of equal medicinal value.

The liquorice plant (*Glycyrrhiza glabra*) grows wild in some parts of the north and east coast of Cyprus. Two samples, called Lapithos and Famagusta, from the place of their origin, gave on analyses the following figures respectively: — Moisture 8.4, and 7.7 %; ash 7.8 and 6.0 %, extract on maceration with chloroform water 27.1 and 23.6 %, glycyrrhizin 10.2 and 9.9 %.

**TOBACCO GROWING IN CYPRUS.** — After the British occupation tobacco-growing was abandoned in the island, and the tobacco used imported from Macedonia. Owing to the rises in the price of tobacco of late years its cultivation has recently been taken up again and, in 1917, a yield of 12 000 bales was expected. Since 1914 the Agricultural Department of Cyprus has been undertaking a series of tobacco growing experiments in different parts of the island with the Samsoun, Kavallas, Xanthi and Trebizond varieties. The results improved each year and were entirely satisfactory. About  $\frac{1}{3}$  of the tobacco now produced in Cyprus is made into "Latakia", or fumed tobacco by fumigation for four or five months. This process was introduced into the island by Syrian refugees and with it fermentation, selection of the leaf, etc. require neither great skill nor care, and became of secondary importance. Latakia tobacco exported into England sold well there. A wild plant, elecampane, locally known as "gonisos", grows very abundantly in the island and is well suited to the fumigation process.

**SUNFLOWER STEMS FROM RHODESIA.** — The cultivation of sunflowers for seed production is increasing in Rhodesia. In 1916 it occupied 1 766 acres and yielded 500 tons of seed. It should be possible to extend its cultivation much more and to make an additional profit from the stems. The sample sent to the Imperial Institute for examination consisted of main stems about 6 ft. long,  $1\frac{1}{2}$  to  $1\frac{3}{4}$  in. in diameter at the root and  $\frac{1}{2}$  to  $\frac{3}{4}$  in at the top, containing a firm, white pith with a specific gravity of 0.043. The constituents of the dry pith were:— ash 18.6 %, proteins

3.4 %, fat 1.1 %, fibre 21.8 %. As compared with maize pith it contains much more ash and much less fibre. It might be used as a food for cattle, but it must be remembered that the Division of Chemistry of the United States Department of Agriculture (*Bulletin* No. 50, p. 27) has shown the food value of maize stems to be increased by the removal of the pith, which is the least digestible part and is very absorptive. Sunflower pith contains too little cellulose to be used for the extraction of this product. Its fibre is too short and brittle to replace sola (*Aeschynomene aspera*) pith in the manufacture of sun-helmets. The entire stems yield 37 to 38 % of pulp which gives a fairly good paper which does not, however, bleach well. If the pith is removed from the chopped stem by scraping and winnowing, 36 % of a pulp is obtained which gives a better paper, but also does not bleach well.

The stems examined contained 10.3 % of moisture and 10.7 % of ash of the following composition:—potash 49.6 %, soda 2.3 %, phosphoric acid 1.5 %. The best use to which these stems can be put is to chop them up finely and spread them as manure, since they contain about 5 % of potash, or else to burn them and use the ash as a potassic fertiliser or for the extraction of potash, as is done in Russia.

#### RAFFIA OR BASS: ITS PRODUCTION, PREPARATION AND UTILISATION.

— Raffia or bass, used for tying plants and in grafting is obtained chiefly from *Raphia pedunculata* of Madagascar, which is essentially a coast species. The principal centres of production of the fibre are the provinces of Majunga, Nossy-Bé and Analalava, and the east coast between Tamatave and Vatomandry. The same species also occurs in East Africa. Other palms also yield raffia, but of a quality inferior to that of Madagascar. The most important of these are:—*R. vinifera* (= *R. taedigera*), abundant in many parts of West Africa, *R. Laurentii*, *R. Gentilii*, *R. Munbutorum*, *R. Sese*, which with *R. vinifera* and other species occurs in large numbers in the Belgian Congo, *R. longiflora* of the Ivory Coast, etc.

*R. pedunculata* can be used for the extraction of fibre when about 15 years old and attains its maximum yield when 40 to 50 years old, when fructification begins. The raffia strip consists of the leaf epidermis, which is strongly thickened on the exterior and bands of sclerenchymatous cells immediately beneath it. In *R. pedunculata* these bands of sclerenchyma are separated from one another by one, rarely two, thin-walled parenchymatous cells. A palm gives on the average 10 leaves a year, but as some are left to develop, only an average of 6 is cut, weighing altogether about 225 lb. and yielding 3.22 % of dry raffia, or about 7 ½ lb. a year. Before the war the price of raffia at Tamatave was from £ 18 to £ 24 per metric ton. In 1914, 4 424 metric tons of raffia with a value of £ 97 329 were exported from Madagascar. The raffia trade is also beginning to develop in West Africa and in some parts of East Africa. Raffia is used in Madagascar for the manufacture of relatively fine fabrics (made with the fibre alone or mixed with cotton or silk), of mats known as "rabannas", of hats, etc. In Zanzibar sacks are made of it, in France mats, carpets, baskets, curtains, etc. It dyes easily.

"WILD OLIVE" FRUITS. (*Ximenia americana*) FROM SOUTH AFRICA (1). — This species, widely distributed in tropical Africa, India, Ceylon, Brazil, the West Indies and the tropics generally, has fruit known by different names according to the district in which it is found (wild lime, mountain plum, seaside plum, citron of the sea, etc.). The natives of the various countries and different writers disagree in the properties attributed to it. Some say it is edible (WATT, SCHWEINFURTH), others that it smells of prussic acid and that no animal will touch it, and others (SAFFORD) that it is much relished by a species of dove. There is also much diversity of opinion with respect to the kernels of the fruit which are edible according to some, purgative or poisonous according to others. A sample from South Africa was examined at the Imperial Institute with the following results:— Average weight, of the whole fruit, 1.6 gm., of the kernel, 1.2 gm.; oil yield of the kernel (containing 3.4 % of moisture) 65.6 to 65.8 % (equivalent to 67.9 and 68.1 % from the dry kernels) by extraction with light petroleum and acetone respectively; specific gravity at 15°C., 0.9221 and 0.9220; acid value, 2.1 and 1.6; saponification value 170.4 and 172.7; iodine value, 93.6 and 88.8 %; unsaponifiable matter 2.9 % including 2 % of a rubber-like substance which makes the oil very viscous and makes it uncertain whether it could be used for commercial purposes (lubricating, soap-making, etc.) before technical trials on a large scale have been made. The oil is non-drying. The rubber-like substance does not appear suitable as a rubber substitute. An analysis of the meal gave the following results:— Moisture 6.2 %; crude protein 38.8 % of which 33.4 % were true proteins and 5.4 % other nitrogenous substances; fat 5.3 %; starch, etc. (by difference) 38.1 %; fibre 6.3 %; ash 5.3 %; nutrient ratio 1:1.3; food units 148. It contains no cyanogenetic glucosides. It is very rich in protein, but as feeding trials in Germany did not give very good results, it would be well to make further trials before deciding the question definitely.

THREE NEW OIL SEEDS FROM WEST AFRICA. — These seeds are known as "N'gore nuts" (*Ongokea Gore*), "N'kamba nuts" (*Heisteria* sp.), and "Strephonema kernels" (*Strephonema* sp.). As these species have only been identified botanically by the fruit they are uncertain or incomplete.

The results of analyses of the oils and cakes are given in Table III. The oil of the first species (yield, 70.7 % of the dry kernels) is of a dark colour and has an unpleasant smell. It is viscous, and may be used for lubricating, soap-making, etc.; it is non-drying. The oil of the second species (yield, 16.3 % of the dry kernels) is non-drying and could be used for various industrial purposes. The fat of the third species (yield, 41.8 % of the dry kernels) melts at 29°C., contains 6.9 % of glycerin, and has a neutralisation value of fatty acids of 183.2. None of the meals contain alkaloids or cyanogenetic glucosides, but that of N'kamba nuts appears to contain saponin and that of Strephonema kernels a considerable quantity of tannin (a sample contained 7.3 % of moisture, 44.3 % of matter insoluble in water, 17.7 % of non-tannin extractive matter, 30.7 % of tannin,

(1) See also R. Sep., 1918, No. 985. (Ed.).

3.3 % of ash, tintometer readings for a 0.5 % tannin solution in a 1 cm. cell, red 7.4, yellow 15.9). It seems unlikely that this meal may be used as a tanning material or for the manufacture of tanning extract, but the extract, which is dark purple-red, would give a dark-coloured leather.

TABLE II. — *Properties of the three oils and the meals corresponding to them.*

INDIAN TRADE IN OIL SEEDS. — The annual production of oil seeds in India is well over 5 million tons of a value exceeding £ 50 000 000. The paper under review is divided into two parts, one which treats of the trade generally, and one dealing in detail with each seed, its oil and by-products, namely :— cotton, linseed, niger seed (*Quizotia abyssinica*), rape (*Brassica campestris*), Indian rape (*Eruca sativa*), mustard, poppy, ground nuts, sesame, castor seed, mowra, mahua or mowa (*Bassia latifolia*, *B. longifolia*, *B. butyracea*), copra, and coconut oil. A table gives the world's trade in these oils and the Indian exports for 1913-14, and their importation into the chief countries consuming them.

A POSSIBLE NEW SOURCE OF THYMOL. — Before the war thymol was obtained commercially only from ajowan oil, distilled from ajowan seeds (*Carum copticum*) which were exported for this purpose from India to Germany.

Among the plants considered as a possible source of thymol is *Ocimum*

*viride*, a native of West Africa which has been introduced into India, Cyprus, and the West Indies. In the wild state this plant reaches a height of 3 ft. to 6 ft., and is perennial. It is sometimes known as "mosquito plant" because it is supposed to keep these insects away. Several samples of *O. viride* leaves from Nigeria and Sierra Leone were examined at the Imperial Institute and, on distillation 0.35 to 1.2 % of essential oil containing 32 to 65 % of thymol was obtained. The Institute obtained seed of this species from Sierra Leone and distributed it in Seychelles, Cyprus and the East Africa Protectorate. The plant did well in Seychelles, and two samples of oil distilled locally were examined at the Imperial Institute. Leaves from four month old plants which had just started flowering gave, on distillation, 0.5 % of oil. Four months later the bushes were 6 ft. high. By distilling the upper 8 in. of the shoots 0.45 % of oil was obtained. The total yield of oil was nearly 3 ½ tons per acre. Five or six cuttings a year may be made. The two oils, from the leaves and the stems respectively, had the following properties:— specific gravity at 15° C., 0.942 and 0.924; optical rotation  $\alpha_D + 105'$  and  $+ 0.60^\circ$ ; phenols, 62 % and 52 %; solubility in alcohol, soluble in 3.1 vols. of 70 % alcohol at 15° C. and insoluble in 20 or less vols. of 70 % alcohol, but soluble in 1.4 vols. of 80 % alcohol at 15° C. The phenols in both oils seem to consist entirely of thymol.

INDIAN HENBANE (*Hyoscyamus muticus*). — This plant is now the chief source of atropine, and is obtained commercially from Egypt and the Soudan. The species also occurs commonly in India. A sample from India examined at the Imperial Institute a few years ago contained only 0.1 % of total alkaloid, much less than is found in the Egyptian plants. A sample of Indian henbane (probably *H. muticus*) examined by BARNES in 1916 contained 0.827 % of mydriatic alkaloids. A specimen grown at the Koilpatti Agricultural Station, Madras, and examined by the Imperial Institute in 1916 yielded 0.61 % of total alkaloids (equivalent to 0.66 % of the dry material) which crystallised easily and consisted of hyoscyamine. The results of this cultivation test were, therefore, satisfactory.

BAOBAB WOOD AND BARK FROM SOUTH AFRICA. — Baobab (*Adansonia digitata*) occurs frequently in tropical Africa and India, and has been introduced into the West Indies. The fibre, extracted from the inner bark, is used by the natives for making ropes and sacking, and small quantities are occasionally sent to England from the West Indies for use in the manufacture of paper. The Imperial Institute examined samples sent from South Africa in 1917 to ascertain their value for paper-making. The air-dried wood contained 10.2 % of moisture and 52.5 % of cellulose. The fibres were 0.7 to 3.2 mm. long, but mostly from 1.5 to 2.5 mm. On boiling with caustic soda 48 to 50 % of dry pulp were obtained. The air-dried bark, contained 9.2 % of moisture and 44 % of cellulose. The fibre was from 1.0 to 4.6 mm. long, but mostly 1.7 to 2.4 mm. Boiling it with caustic soda gave 27 % of dry pulp. From the inner bark alone was obtained 33 % of excellent quality pulp which, however, did not bleach satisfactorily. On the other hand, if the whole bark is used the pulp contains sclerenchymatous cells which are not removed by washing and make the

pulp gritty and too hard to be used. The pulp from the wood is less good than that from the inner bark and is less satisfactory for paper-making. Owing to the lightness and bulkiness of the wood it would have to be made into pulp in the countries producing it.

1076 - **Australian Interstate Conference of Agricultural Scientists.** — In *The Journal of the Department of Agriculture of South Australia*, Vol. XXI, No. 5, pp. 388-396. Adelaide, 1917.

AGRICULTURAL  
SHOWS  
AND  
CONGRESSES

A Conference attended by agricultural scientists from all the Australian States convened by the Federal Government at the instance of the Advisory Council of Science and Industry, was held in Melbourne from November 9th to November 16th, 1917. A number of papers dealing with different aspects of agricultural science were read and discussed. The following resolutions were carried by the Conference and forwarded to the Executive Committee of the Advisory Council of Science and Industry of the Commonwealth of Australia.

I. — That a "Seed Improvement Committee" be formed, which should, among other matters, deal with: — a) The nomenclature of cultivated varieties of farm crops; b) the elimination of undesirable varieties of crops; c) the exchange and dissemination of seed samples for research work; d) the recommendation of money grants to approved State or other Institutions for work in connection with seed improvement and the introduction of improved varieties of crops.

II. — That in view of the benefits to be derived from the systematic introduction of seeds and plants into the Commonwealth and to ensure more economy of effort in this direction on the part of all the States, this Conference is of the opinion that as soon as practicable a Plant Introduction Bureau should be established, the functions of which would include: — 1) Arrangements for the introduction of new and useful agricultural plants from other countries into the Commonwealth; 2) the systematic testing of these introduced plants in cooperation with State Experiment Farms; 3) the systematic recording of the results of such tests.

III. — That each State Department of Agriculture should continue or initiate the work of improvement and selection of its cultivated crops as part of its regular work, and that such work of improvement be on uniform lines in all the States.

IV. — That the rust in cereals, particularly black rust in wheat, which is common in all the States, and in some seasons largely reduces the yields, be made the subject of a special investigation in connection with plant-breeding.

V. — That the Executive Committee of the Advisory Council be asked to arrange for an annual meeting of plant-breeders from the different States, with a view to co-ordinating their work and arriving at a uniform policy without interfering with individual methods. The meeting to be fixed at a convenient season of the year (July).

VI. — That an organisation should be established to deal with the collection, propagation, improvement, and cultivation in suitable areas of the most promising indigenous grasses and fodder plants.

VII. — That it is advisable to closely investigate the tobacco industry in Australia, both in the interests of the producer and with a view to retaining locally the profits of manufacture.

VIII. — That in view of the high prices ruling for fibre products and the desirability of making Australia self-contained in the production of fibre, a thorough investigation be made into the possibilities of fibre cultivation in Australia, particularly flax and sisal hemp, and the possibilities of producing these fibres for local manufacture or for export.

IX. — That the Advisory Council of Science and Industry be asked to ascertain whether the British Government would be prepared to purchase dew-retted flax fibre from Australia in 1919, and if so, what quantities and at what price f. o. b.

X. — The Conference is of opinion that the prospect of commercial production of power alcohol from certain crops is promising, and suggests that special experiments should be arranged by the Advisory Council of Science and Industry to determine the actual yields of alcohol obtainable from these crops, including sorghums in various stages of development.

XI. — That the Conference welcomes the proposal of the advisory Council to investigate the utilisation of Australian phosphates, and suggests that this investigation should include manurial trials, particularly on pasture lands in those of the States which possess such phosphates.

XII. — That in view of the need for a supply of scientific investigators into agricultural and pastoral problems the Advisory Council of Science and Industry be requested to direct the attention of the various Australian Universities to the subject.

XIII. — In view of the prominent position occupied by the United States of America in scientific and practical agriculture, and of the similarity of the climatic and economic conditions of that country to those of Australia, this Conference recommends the early appointment of a permanent agricultural representative from Australia to the United States, whose duties should include keeping Australia in touch with improved scientific and practical methods in agriculture and the supply of promising varieties of cereals and other crops.

XIV. — That the Conference expresses its appreciation of the action of the Executive Committee of the Advisory Council of Science and Industry in calling it together, and is confident that the opportunity of meeting and consulting together thus afforded to agricultural scientists from the different States will be beneficial to agricultural progress in Australia.

## CROPS AND CULTIVATION.

### AGRICULTURAL METEOROLOGY

1077 — Investigations into the General Movements of the Atmosphere. — GARRIGOU-LAGRANGE, P., in *Comptes rendus de l'Académie des Sciences*, Vol. CLXVII, No. 4, pp. 170-172. Paris, 1918.

The general movements of the atmosphere affect, during periods of greater or lesser length and in well-marked directions, whole zones of the hemisphere. In every season the general circulation is characterised by

areas of high and low pressure, registered at the Signal Office of Washington. As a result of the general movement in question these are subjected to transformations and displacements which rise or fall. The resulting effects in each district are noted on the charts of the various meteorological stations. Unfortunately the complexity and duration of the phenomenon make it very hard to understand, and to recognise it is necessary to examine a long series of charts. To make this easier the author has evolved an original method of examination. Each chart is considered as an instantaneous photo of the phenomenon, and the charts are joined to each other by the requisite number of intermediate conditions. When reproduced on a cinematograph film and projected, these series of charts give the impression of a fairly rapid movement, the different phases of which can be easily distinguished. It has thus been possible to prove :— 1) that the low and high pressures (at the surface of Europe and North America) follow a trajectory, sometimes to the north on the 60th parallel, sometimes to the south on the 30th, so that, in a given region, the atmosphere is subjected to a sort of respiration as a result of the alternate rise and fall of this trajectory ; 2) that the displacements of the trajectory, involving, at the time of falls, the formation of elongated isobars which precede the gusts, make it possible to determine exactly the periods when these are to be feared ; 3) that these phenomena are reproduced in accordance with a fairly well-defined law of periodicity.

The study analysed has shown astronomical relations similar to those shown by POINCARÉ in his study on the displacement of the field of the trade-winds. Both above and below the 30th parallel, the action of the moon usually draws with it, in aggregate movements, vast areas of the hemisphere. Thus, by the help of this periodicity it is possible to connect with the movements of the moon (chiefly in declination) the general movements of the atmosphere and, in each region, the displacement of the trajectory from the centre of depression. If the movements on a given meridian and those near it are known it is also possible to deduct the probable succession of the phenomena during one day, and to state, for example, that during that period the centres of depression will tend to pass to the north of the point of observation, that this movement will be more marked towards the evening, etc.

1078 — **The Effect of Weather on the Yields of Potatoes, Wheat and Maize, in Ohio, U. S. A.** — WARREN SMITH, J., in the *Monthly Weather Review*, Vol. XLII, No. 2, pp. 78-87 + 15 Figs.; Vol. XLIII, No. 5, pp. 222-236 + 23 Figs.; Vol. XLIV, No. 2, pp. 74-75. Washington, February, 1914; May, 1915; February, 1916.

The author has made use of the abundant meteorological and agromonomical statistical data collected by the Weather Bureau, Bureau of Statistics and Bureau of Crop Estimates of the U. S. Department of Agriculture to investigate the influence of weather on the distribution and yields of potatoes, winter wheat, and maize in the State of Ohio.

I. — **POTATOES.** — The most important weather factor for this plant is *normal temperature* during July ; if it exceeds normal the yield will be much below average. The coefficient of negative correlation is very high :

$r = -0.51$  (1). When  $r$  is calculated for the other months or groups of months the values obtained are always negative, but less high than those for July. They are: — May,  $-0.10$ ; June,  $-0.22$ ; July,  $-0.51$ ; August,  $-0.31$ ; September,  $-0.21$ ; October,  $-0.11$ ; June and July combined,  $-0.50$ ; July and August combined,  $-0.050$ ; June, July and August combined,  $-0.49$ .

The effect of the rainfall is much less marked than that of temperature. Only July and August combined have a positive and fairly marked correlation coefficient,  $0.33$  and  $0.37$  respectively, values 4 and 5 times that of the probable error. Thus, for a good potato harvest in Ohio, July should be cool and damp.

A closer examination of data for the counties of Franklin, Madison, and Pickaway, based on meteorological values for periods of ten days as well as for those of one month, not only confirmed the statements made with respect to the whole of Ohio, but showed yet more clearly the special importance of the first ten days of July. The correlation coefficient between the yield of potatoes and the temperature during these ten days was  $0.4$ , much above that of the other ten day periods.

It is important to know at what stage the plant is particularly sensitive or exacting with respect to the weather factors, in other words, to determine the critical stage of the potato with regard to temperature and moisture (2). For this purpose the phenological and meteorological observations made by Mr. T. MCKESSELL at Wauseon (Fulton County, Ohio) from 1883 to 1912, proved exceedingly useful. The vegetative period of the potato is subdivided into three sub-periods:— 1) from planting to the appearance above ground; 2) from the appearance above ground to flowering; 3) from flowering to ripening. For these three sub-periods and for the two ten-day periods, before and after flowering the following correlation coefficients between yield and rainfall on the one hand and yield and temperature on the other were found:—

1) *From planting to appearance above ground*:— rainfall  $-0.06$ , temperature  $+0.03$ .

2) *From appearance, above ground to flowering*:— rainfall  $+0.33$ , temperature  $+0.24$ .

3) *From flowering to ripening*:— rainfall  $+0.18$ , temperature  $+0.16$ .

4) *Ten days before ripening*:— rainfall  $+0.09$ , temperature  $+0.17$ .

5) *Ten days after ripening*:— rainfall  $-0.07$ , temperature  $-0.30$ .

For the rainfall the maximum value of  $r$  ( $0.33$ ) occurs between the appearance of the shoot above ground and flowering, and is positive.

(1) To calculate the correlation coefficient  $r$ , the formula used is  $r = \frac{\sum \sigma \sigma'}{\sqrt{\sum \sigma^2 \sum \sigma'^2}}$ , where

$\sigma$  represents the deviation from the mean precipitation or temperature and  $\sigma'$  the deviation from the mean yield in grain. By these means are obtained, for  $r$ , values between  $+1$  (perfect positive correlation) and  $-1$  (perfect negative correlation). Values above  $+0.5$  or below  $-0.5$ , therefore show a high correlation coefficient. (Ed.)

(2) See R. March, 1918, No. 256. (Ed.)

For the temperature the maximum value of  $r$  ( $-0.30$ ) occurs during the same period and is negative.

Even without possessing phenological data it may be assumed that the first ten days of July, or any other ten-day period in which a high negative correlation coefficient is found for the various counties of Ohio, correspond to the ten-day period immediately following the flowering stage.

II. — WINTER WHEAT. — For this plant the temperature of March is the most important factor. When this temperature exceeds the normal the probability of the yield being above the average is 94 %, but when the temperature is below the normal this probability drops to 25 %. To obtain a good wheat harvest in Ohio, March should be rather warm. Contrary to the general opinion, snowfalls during this month are always detrimental to wheat.

III. — MAIZE. — The dominant factor for maize is rain in July, with a positive correlation coefficient of 0.59. When, during this month, the rainfall is 1 in. above the normal, the probability of a yield superior to the average is 92 %, but if the rainfall is below the normal, this probability is only 13 %.

The average yield per acre for all the years when the rainfall in July was less than 3 in. was 30.3 bushels, but when the rainfall in this month was 5 in. or more the average yield was 38.1 bushels per acre.

A closer examination of averages of ten-day periods as well as of one month showed the importance of certain ten-day periods. Thus, in the county of Wayno, the highest positive correlation coefficient between rainfall and yield occurs during the second ten-day period of July and equals 0.71; in the counties of Franklin, Madison, and Pickaway (central Ohio) it is 0.52 and occurs during the first ten days of August, etc.

By phenological and meteorological observations at Wauseon, it was possible to determine for maize, as for the potato, the date of the critical stage with respect to weather. Below are the correlation coefficients found between yield and rainfall and yield and temperature respectively for the sub-periods considered above, the ten days before planting and the ten days before and after flowering: —

- 1) Ten days before planting: — rainfall,  $+0.01$ ; temperature,  $-0.03$ .
- 2) From planting to appearance above ground: — rainfall,  $-0.06$ ; temperature,  $-0.03$ .
- 3) From appearance above ground to flowering: — rainfall,  $-0.03$ ; temperature,  $+0.18$ .
- 4) From flowering to ripening: — rainfall,  $+0.29$ ; temperature,  $+0.08$ .
- 5) Ten days before flowering: — rainfall,  $+0.20$ ; temperature,  $-0.003$ .
- 6) Ten days after flowering: — rainfall,  $+0.74$ ; temperature,  $-0.28$ .

The critical period for rain is, therefore, the ten days following flowering, and the correlation coefficient,  $+0.74$ , is very high.

The effect of temperature is much less marked and only during the

ten days after flowering is a value exceeding the probable error found for the correlation coefficient. At this period high temperatures are detrimental to maize.

To sum up, to obtain a good maize harvest in Ohio abundant rain and moderate temperatures are necessary during the ten days following flowering.

SOIL PHYSICS,  
CHEMISTRY  
AND  
MICROBIOLOGY

1079 - **The Reserves of Soil Water During Drought.** — DUMONT, J., in *Comptes rendus de l'Académie des Sciences*, Vol. CLXVII, No. 7, pp. 278-280 + 2 Tables. Paris, 1918.

In July, in the experiment field of the Agricultural Station at Grignon, in plots containing both fertilised and unfertilised cereals and beets, the author estimated the reserves of soil water at various depths between the surface and 80 cm. (31.44 inches). He proved that, besides the influence due to the difference in crops, there was also clearly another one due to the fertiliser. Thus taking as a basis for calculation the average percentage of moisture and the weight of the layer of soil of 1 hectare (2.47 acres), the total aqueous reserves are:— 1560 metric tons in the unfertilised beet plot; 1536 tons in the fertilised beet plot; 900-1000 tons in the fertilised cereal (wheat and oats) plot. Fertiliser applied in large quantities and ploughed in maintains a high proportion of moisture (17.8 %) in the soil layer. The average percentage of moisture for the three fertilised plots (beets, wheat, oats) was 15.8, whereas for the unfertilised plot (beets) it was only 10.4.

In spite of the importance of the reserve water in the lower layers of the soil, it is above all the superficial distribution of these reserves that influences the progress of vegetation at the beginning and, consequently, the whole progress of the crop. Once the root system is sufficiently developed the plant's supply of water is more assured and it is then better able to protect itself against drought. Attention is drawn to the fact, confirmed by observations made over a long period, that, even after a prolonged drought, there is still relatively abundant water in the soil; for example, in 1913, after a long drought, the quantities varied from 720 to 960 metric tons per hectare at a depth of 50 cm. (19.65 inches).

1080 - **Effect of Irrigation Water and Manure on the Nitrates and Total Soluble Salts of the Soil.** — HARRIS, F. S. and BUTT, N. I. (Utah Agricultural Experiment Station), in *Journal of Agricultural Research*, Vol. VII, No. 9, pp. 333-359, + 7 Tables, + 18 Fig., + Bibliography of 17 Publications. Washington, D. C., February 26, 1917.

There is no method available for measuring exactly what portion of the plant food in the soil can be taken up by crops at any given time; the nearest approach is to extract the soil with some solvent and to determine the quantity of plant food in the solution obtained.

In the present paper an attempt has been made to determine the effect of varying quantities of soil moisture and manure on the total soluble salts and nitrates that can be extracted by water from the soil. Some of the soils under investigation were kept in the laboratory, others were allowed to stand for long periods in large tanks, while still others were studied under normal field conditions. Comparisons were also made of cropped with uncropped soils in tanks and in the field. The results are given below.

[1915-1920]

With a sod soil held in the laboratory for 2 ½ years, the total salts and nitrates accumulated most rapidly with a moisture content between 23 and 28 per cent.

Cropped and uncropped soil kept in large tanks under controlled moisture conditions showed a decrease in nitrates and total soluble salts as the percentage of moisture increased, the nitrates being particularly low in water-logged soil.

Under field conditions more nitrates were found in both cropped and fallow soils during the summer than just after the corn crop was harvested.

The nitrates of the fallow field soils averaged higher with a manuring of either 5 or 15 tons to the acre than with no manure, but on the cropped soil, although the 15-ton application of manure resulted in more nitrates than no manure, the 5-ton did not. The fallow soil showed the effect of the manure on the nitrates more in the top 2 or 3 feet than at lower depths.

The highest soluble-salt content of fallow soil was on plots manured at the rate of 5 tons to the acre; the lowest was on plots receiving 15 tons. The corresponding high and low points in cropped soil were on plots receiving no manure and 5 tons to the acre, respectively.

Unirrigated land contained more nitrates than irrigated on both cropped and uncropped plots. Increasing the irrigation water applied to the soil decreased its nitrate content. The total soluble salts in cropped plots decreased as the water applied increased and in fallow soil an application of 40 inches of water resulted in less salts than where no irrigation water was added. The treatment affected the salts more in the surface foot than at greater depths with small irrigations, but when 20 inches of water or more were applied some of the salts seemed to have moved below 10 feet in depth. Large irrigations decreased the soluble salts in cropped more rapidly than it did in fallow soils.

Manuring or irrigating the soil affected the nitrates relatively more than the total salts.

In unmanured soil the nitrate content was about twice as great with a fallow as with a crop, and in manured, it was about three times as great.

The ratio of total soluble salts to the quantity of sodium nitrate found in a cropped soil rose from 24.5 to 1 without irrigation to 37.5 to 1 when 40 inches of water were used. The ratio in fallow soil increased from 8.9 to 1 with no irrigation water to 16.2 to 1 with 40 inches.

The field results do not indicate a close relationship between the crop yield and the total soluble salt or the nitrate content of the soil if the differences between cropped and fallow soils indicate the amounts of these substances which the crop used.

After a consideration of both pot and field experiments, it is evident that the soluble salts and especially the nitrates are found in lower concentrations in soils receiving large quantities of irrigation water than in those receiving less water. This is probably due in part to the leaching action of the heavy irrigations as well as to the lower nitrification in the presence of excessive soil moisture.

1081 - **Evaporation from the Surfaces of Water and River-Bed Materials.** — SLEIGHT, R. B. (Assistant Irrigation Engineer, U. S. Department of Agriculture), in the *Journal of Agricultural Research*, Vol. X, No 5, pp 209-261 + 26 Tables + 13 Figs. + 6 Plates + Bibliography of 27 Publications Washington, July 30, 1917

The Irrigation Field Laboratory at Denver, Colorado, where the author carried out his investigations, was established for the purpose of studying, from an engineering point of view, the problems connected with the utilisation of water for irrigation. The laboratory is of such a size and type that natural phenomena may be observed under conditions rather less artificial than is usual in laboratories.

The first investigations made there bore on the action of water and the movement of water through soils. Evaporation plays a large part in the apparent efficiency of the use of irrigation water. As the measurements and data available on evaporation were not considered sufficient for the proposed work, research on this subject was undertaken. The work done in 1916 was confined to the study of evaporation, divided into two parts: — 1) evaporation from water surfaces; 2) evaporation from the surfaces of river-bed materials.

I. — **EVAPORATION FROM WATER SURFACES.** — The following points were studied: — a) variation in the speed of evaporation from pans of varying sizes; b) variation in the speed of evaporation from pans of varying depths; c) comparison between the rate of evaporation of flowing and of still water; d) comparison of the results obtained from different types of so-called standard evaporation pans; e) comparison between the rate of evaporation from round pans and from square pans; f) application of the results obtained with experimental pans to larger water surfaces.

The results are presented, not as formulae which may easily be misinterpreted and applied in cases where their use is not justified, but as graphs based on the original data (given in tables) which show clearly the limits within which these data may be applied, or as coefficients obtained from these graphs. The principal deductions are:—

a) In metal pans from 1 to 12 ft. in diameter sunk in the soil the water surface evaporated during 1 year was from 76.18 to 49.16 inches, or from 154.9 to 100 %. The small tanks had higher day temperatures and lower night temperatures than the bigger ones; the average daily temperatures are almost equal. The effect of the higher day temperatures, however, is greater than that of the lower night temperatures, and results in greater evaporation. For a given wind velocity the air on the surface of a small pan is renewed more often than that on the surface of a large one in the ratio *large diameter : small diameter*, thus increasing the rate of evaporation in the *small pan*.

A study made at Salton Sea by Mr. BIGELOW to determine the law of evaporation by the use of cylindrical pans *with vertical sides almost entirely above the soil* (at Denver they were sunk in the soil) of diameters of from 1 to 12 ft., gave data concerning the rate of evaporation which do not agree with those obtained by the author at Denver, and do not appear to be applicable to large water surfaces.

b) Evaporation was observed in pans of equal diameter but of depths

varying from 0.25 ft. to 5.75 ft. and the results for each group expressed in percentages of the deepest pan. It was found that during the hot season the rate of evaporation is greater in the shallow pans, but that in the cool season the opposite holds good. The differences are due to the temperature of the water and are not very large, but for general use, a tank not less than 2 ft. deep is recommended, as its contents do not become hot or cold so rapidly as those of a shallower tank.

In two tanks containing water of equal depth and with equal exposed area but still in one case and, in the other, kept flowing by a centrifugal pump, it was found, after differences due to temperature had been corrected, that evaporation was greater in the tank with flowing water.

In one set of experiments the difference was due to the evaporation in still water multiplied by 1.072 and, in the other, by 1.086. Although this experiment was limited by the unavoidable low velocity of the water it shows that evaporation from a canal is slightly greater than from still water under exactly the same conditions of exposure, temperature, etc. There does not appear to be any definite relation between evaporation and velocity within the limits of the experiment. To the author's knowledge only one previous experiment has been made on this subject. It was carried out in Spain in 1849 for a short period only and the agitated water evaporated 140 % as compared with the still water. Corrections for differences in temperature do not seem to have been made.

d) The evaporation from a standard pan used at the Class A stations of the U. S. Weather Bureau when above the ground, was  $1\frac{1}{2}$  times as great as that from a cylindrical tank 12 ft. in diameter and 3 ft. in depth set 2.75 ft. in the ground.

The evaporation from a PICHE evaporimeter was 181.7 times that of the same tank.

The data obtained with the standard pan are, therefore, not applicable to large water surfaces; this is true to a yet greater extent of those obtained with the PICHE evaporimeter.

e) Experiments were made with two pairs of pans, one circular, the other square, of equal exposed water surface (9.0 sq. ft. in one case and 3.14 sq. ft. in the other), all 3 ft. deep and set in the ground. Taking the mean weekly averages for 1 year, the large square pan evaporated 104.7 % and the small square pan 104.9 % as compared with the circular pan of equal area. This increase in evaporation is due to the fact that, for the square tank, the ratio *perimeter : area* is greater than in the circular tank. No difference was observed between the mean temperatures of the water in the two types.

f) The evaporation from a lake of 17 acres having no outlet, when measured with a floating pan was found to be 108.9 % that of a 12 ft. pan and 86.1 % that of a 3 ft. square pan (*i. e.* equal in area to the floating pan). From comparative investigations made partly with U. S. Geological Survey floating pans and partly with pans of other sizes, the author draws the following conclusions:—

1) Evaporation figures obtained with tanks of a depth of 2 ft. or

more, preferably circular, set in the ground so that a metal rim not exceeding 3 in. projects, and in which the water is kept approximately at the ground level, are the most suitable for use with large open water surfaces.

2) Data obtained with such tanks may be applied suitably to large open water surfaces under the same conditions of wind, atmospheric temperature and moisture, by multiplying the evaporation depth (*i. e.* the depth of water evaporated in a unit of time) of a 2 ft. tank by 0.77 and of tanks of 4, 6, 9 and 12 ft. by 0.84, 0.90, 0.98 and 0.99 respectively. Data obtained with a 3 ft. cubic tank sunk 2.75 ft. in the ground (Fort Collins type) should be multiplied by 0.80, those obtained with a U. S. Geological Survey floating standard, by 0.91, and those obtained with the type used in the Class A stations of the U. S. Weather Bureau, by 0.66.

These results only agree in part with those previously obtained, but no other work has gone so deeply into the subject.

## II. — EVAPORATION FROM THE SURFACE OF RIVER-BED MATERIALS —

*Experimental methods:* — Typical river-bed material was placed in watertight tanks, the surface of the water kept at a fixed level below the surface of the material, and the loss by evaporation measured and expressed in percentage of the loss suffered by a water surface of equal shape and size.

*Results.* — The results are given in tables and diagrams. Among the data obtained are the following: — for a water table 3 in. below the surface of the bed, evaporation varied, according to the material, from 66 to 89 %; for water tables 6, 12, 16 and 24 in. below the surface, evaporation varied from 53.0 to 86.6 %, 24.2 to 82.5 %, 42.0 to 79.8 %, and 11.2 to 68.0 % respectively (for the two determinations only two kinds of material were used, for the others, five).

Unpublished data obtained in 1915 by Mr. DIESEM at North Platte furnish a positive control of those obtained by the author.

1082 — *Irrigation of Alfalfa in Imperial Valley, California* (1). — FACKARD, W. C., in the *University of California Publications; College of Agriculture, Agricultural Experiment Station Bulletin* No. 284, pp. 67-84 + 5 Figs. + 5 Diagrams. Berkeley, California, September, 1917.

Recent investigations have shown the desirability of modifying the methods of irrigating alfalfa in the Imperial Valley so as to increase the yields. The bulletin under consideration describes investigations into the development of the roots in various types of soil with different quantities of water to determine the effect of irrigation on the roots. For this purpose the alfalfa roots were removed from a plot 3 ft. square, washed, air-dried, and weighed.

It was found that from 80 to 90 % of the fine roots develop in the upper 4 ft. of the soil, where the land receives frequent surface irrigation. Abundant irrigation favours the development of roots to a depth of 5 ft., but, under ordinary conditions, most of the fine roots develop in the upper stratum. Under the experimental conditions most of the fine roots developed in the first 2 ft., showing that special attention should be paid to the upper stratum no matter what system of irrigation is adopted.

(1) For the irrigation of alfalfa in the Sacramento Valley, California, see R., May, 1918, No. 507. (Ed.)

The presence of organic matter has a marked effect on the development of the feeding roots; this was observed each time the roots met a layer containing much organic matter. The larger roots often pass through a sandy stratum containing little organic matter without developing many rootlets till they reach a richer sub-soil. The soils of the Imperial Valley require much organic matter, and this need should be met wherever possible. The two above facts are clearly illustrated by diagrams.

It was also observed that if the water table rises to more than 4 ft. from the surface the roots rot if immersed in the water for a long time (2 to 3 months). If the water table drops new rootlets develop from the healthy part of the plant which has not been destroyed by the water. If the water level rises to 3 ft. from the surface all but the more resistant plants are killed. To obtain satisfactory yields of alfalfa a large amount of water must be supplied frequently during the season so as to prevent drying of the surface soil on one hand and water-logging of the soil on the other. This may be accomplished by adapting the grade of the land, the frequency of irrigation, the size of the field and the head of water used to the type of soil to be cultivated.

In sandy soil the lands for irrigation should not exceed  $\frac{1}{8}$  mile in length and 25 to 30 ft. in width. If the soil is very sandy the lands should be narrow and short and a large head of water should be used to assure quick irrigation. The great danger lies in the application of too much water, especially if the soil is sand overlaying clay, as in this case a high water table is formed.

Medium soils are easily irrigated. If the alfalfa does not do well the soil should be examined with a augur or a spade. If the top soil appears dry before irrigation it is well to give a slight additional irrigation between cuttings, but if the lower strata be saturated the recommendations given for compact or clay soils should be followed.

In compact soils the problem is to let the water pass deep into the soil in sufficient quantity to maintain rapid growth. In such soils, the sub-soil is frequently found to be dry at a depth of from 2  $\frac{1}{2}$  to 3 ft. To obtain proper penetration it is advisable:— 1) to make the lands  $\frac{1}{8}$  to  $\frac{1}{4}$  mile long; on comparatively flat land the borders should be from 50 to 100 ft. apart, but when the land is at all steep they should be only 25 to 30 ft. wide; 2) to run a comparatively small head for a long time. Fields yielding from 2  $\frac{1}{2}$  to 3 tons per acre per year have produced double the quantity with this system of irrigation. In this way also the water penetrates to 5 or 6 ft. when a larger head of water will only penetrate to 3 ft. The grade should not be more than about 10 %. The lower ends should be drained to prevent accumulation of water.

**1083 - Drainage Instruction and Demonstration in Canada.**— I. MITCHELL, J. W. (Supervisor under the Agricultural Instruction Act in the Maritime Provinces). — II. SAVOIE F. N. (Secretary, Department of Agriculture). — III. SCOTT, W. H. (Director of Drainage Demonstrations, Ontario Agricultural College). — IV. ENGLISH, H. O. 'Crop and Soil Instructor', in *The Agricultural Gazette of Canada*, Vol. V, No 7, pp. 680-683. Ottawa, July, 1918.

I. — THE MARITIME PROVINCES. — In Nova Scotia drainage work

is done by the province, which uses a Buckage traction ditching machine. The work is done at the request of the farmers, on plans drawn up by the Drainage Service, and is paid on a commercial basis.

The province of New Brunswick owns a ditching machine and from July to October, 1917, dug 1 435 rods to an average depth of 2 ½ ft. The official price per rod was 30 cents, including the laying of the tile, and did not nearly pay the actual cost.

There is much drainage work to be done in all parts of Prince Edward Island. Last year the Department of Agriculture bought a ditching machine which has proved very satisfactory. In each case the drainage plans are drawn up by the Department.

II. — PROVINCE OF QUEBEC. — Drainage is encouraged by the Department of Agriculture of the province which draws up the plans and executes the work. The surveys are made by six instructors who, in 1917, visited 79 farms and made plans for draining 2 154 acres. The province has bought two Buckage ditching machines. No charge is made for work done on 5 acres or less, but the farmer pays for the board of the conductor and his assistant; for 5 to 20 acres the farmer pays the salary of the conductor as well as the board of the two men. Twenty acres are the maximum area which may be covered for any farmer.

In 1917, 12 963 ft. of drainage were dug. This amount was below the average because of the unfavourable season and the difficulty of replacing broken parts. In the future the Minister of Agriculture for Quebec will make grants to groups of farmers or to Associations to enable them to buy ditching machines.

III. — ONTARIO. — In order to increase the knowledge of drainage the Ontario Agricultural College prepared a cinematograph film illustrating different drainage operations. The province has two ditching machines as well as concrete tile making machines, which are placed at the disposal of farmers for their drainage work on payment of a nominal fee to cover some of the expenses incurred.

IV. — BRITISH COLUMBIA. — In 1917 the Department of Agriculture of this province bought an 8-horse Cyclone ditcher. According to the tests made this machine is not suitable for digging ditches at a depth exceeding 2 ft.

TILLAGE AND  
METHODS OF  
CULTIVATION

1084 - **Dry Farm Crop Rotations and Cultural Methods, in U. S. A.** — ATKINSON, A., STEPHENS, J. M. and MORGAN, G. W., in the *University of Montana Agricultural Experiment Station, Bulletin No. 116*, pp. 54 + 19 Tables + 6 Figs. Bozeman, Montana, March, 1917.

This bulletin gives the results of experiments on crop-rotations suitable to dry farming carried out by the Montana Experiment Station in co-operation with the Bureau of Plant Industry of the U. S. Department of Agriculture. The experiments were made at the Judith Basin Sub-station and the Huntley Experiment Farm.

The average annual rainfall at Judith Basin during the last 18 years was 16.66 in., 10.90 of which fell between April 1 and September 30. The average annual rainfall at Huntley was 13.74 in., 8.42 of which fell

between April 1 and September 30. At both stations the heaviest average rainfall occurs in May and June. The total evaporation from April to August inclusively amounted to an average of 25.049 in. at Judith Basin during the last 8 years and 20.397 in. at Huntley during the last 4 years.

The average temperature from April to September inclusively is 54.8° F. at Judith Basin and 59.7° F. at Huntley. The greatest deviation from the ordinary monthly average occurs in June at both stations.

The experiments were conducted on the same basis at the two stations, the normal principal crops being cultivated in various rotations, by different methods of seed-bed preparation and systems of continuous cropping.

The experiment plots were  $\frac{1}{10}$  of an acre in area, separated from each other by paths 4 feet wide. Two to six year rotations were tested. The cultural methods were the same at both stations: — autumn ploughing (to a depth of 7 inches at Judith Basin and 8 inches at Huntley, one plot at each station being ploughed only 4 inches deep) left rough throughout the winter except when autumn seed was sown; spring ploughing for spring seed (spring ploughing for maize being done immediately before sowing); listing for spring grain at the same time as autumn ploughing (for winter wheat the land was levelled just before seeding; listing for maize was done in spring); subsoiling, the subsoil plough following the plough; disking, usually just before sowing; plots to be left fallow were ploughed in May or early June and cultivated sufficiently to prevent subsequent weed growth. When green manure was used the ground was ploughed in autumn and the crops ploughed under when they reached their maximum growth. After sod crops — brome and alfalfa — it was found necessary to plough twice at both stations, first to about 3 inches, and later to about 7 or 8 inches. After ploughing, all the plots were cultivated sufficiently to give a good seed-bed, plots with the same method of seed-bed preparation being given uniform cultivation.

The rotations tested may be divided into four groups: — 1) 2-year rotation comparing fallow with maize land as a preparation for spring wheat and oats; 2) 3-year rotation containing two of spring cereal crops, wheat, oats, or barley, and either maize or fallow in the third year; 3) 3 and 4-year rotation including one green manure crop (rye, peas, or sweet clover), followed by a small grain crop, then, in the 3-year rotation, maize; in the 4-year rotation a second small grain crop came between the maize and green manure; 4) 5 and 6-year rotations comparing various sod crops and their effect on the following crops.

The results of the experiments are given in detail with many tables; they may be summarised as follows: —

In the 2-year rotation containing grains and maize or spring grains and fallow, the highest profit was obtained with the system containing maize.

In the 3-year rotation, containing spring grain and either maize or fallow the third year, maize proved more profitable than fallow.

In the 3-year rotation of 2 cereal crops and 1 of maize it was found more profitable to disc the maize land than to plough it as a preparation for one of the small grain crops. In rotations containing green manure

rye was found more satisfactory than peas for this purpose. The 3-year rotation containing green manure was less profitable than the 4-year rotation containing green manure. Three and four year rotations including green manure gave less satisfactory results than similar rotations in which clean fallow replaced green manure.

Rotations containing sod crops for two or three years gave comparatively low profits. Brome proved slightly more profitable than alfalfa.

In the continuous cropping experiments with winter wheat, autumn ploughing proved most profitable at Judith Basin and summer fallowing the least profitable. At Huntley the best results for winter wheat were obtained with summer fallowing, the worst with subsoiling.

In the spring wheat and oat series listing gave the most satisfactory results and summer fallowing the least satisfactory ones at Judith Basin; listing was also the most satisfactory method at Huntley.

At Judith Basin maize was most profitable on spring ploughing and least profitable on summer fallow. At Huntley maize did best on spring listing and worst on summer fallow. For flax spring ploughing was the most profitable and summer fallow the least so at Judith Basin, autumn ploughing the most profitable and subsoiling the least profitable at Huntley.

**1085 - Experiments on the Electro-culture of Growing Crops, in Scotland (1). —** HENDRICK<sup>1</sup> (Prof., Aberdeen University), in *The Scottish Journal of Agriculture*, Vol. I, No. 2, pp. 160-171 + 1 Fig. + 4 Tables. Edinburgh, April, 1918.

The experiments described were begun over 9 years ago by Mr. Low, of Balmakewan, on his farm of Mains of Luther, Kincardineshire. He tested on a field scale the effect of a high tension overhead electric discharge distributed on the system of the Agricultural Electrical Discharge Co., Ltd., upon ordinary farm crops. After experiments had been carried out on a large scale for some years upon a number of fields under the ordinary rotation of the farm without any distinct result being obtained, Mr. Low, in order to avoid some of the difficulties and sources of uncertainty encountered in the experimental method previously followed, drew up, in consultation with the author, a plan for a series of plots upon a selected piece of ground of an area of about 6 acres, situated in one of the fields of the farm.

The LODGE NEWMAN apparatus, supplied by the Agricultural Electric Discharge Co., Ltd., was used for producing and distributing the current. By this apparatus an ordinary 200-volt current is transformed by an induction coil into a high tension current of from 60 000 to 100 000 volts. By means of valves patented by Sir OLIVER LODGE a charge is accumulated on the overhead network. These valves allow electricity to pass only in one direction, and so only current of the desired sign can flow to the overhead network, and it is retained there save for leakage and for discharge from the fine radiating wires through the air. The effect is to make the field with the growing crop and the network a leaky condenser, the field and crop being charged with negative electricity while the overhead network has

(1) See also *R.*, January, 1918, No. 10. (*Ed.*)

a positive charge. As the apparatus has already been described on many occasions it need not be mentioned further (1).

The apparatus was installed by the officials of the Agricultural Electric Discharge Co., Ltd., and was on various occasions visited and inspected by their representatives. Improvements were installed at considerable expense by Mr. Low to avoid leakages, etc. In fact, he had adopted all the suggestions made by the society's experts who expressed themselves as quite satisfied with the apparatus and the way it was worked.

The plots were laid out early in 1913 in a fairly level field of good loamy soil. The rotation was turnips, barley, hay, pasture, and oats; in the fourth year the pasture was replaced by potatoes as being of greater interest for the experiment. Ten plots, each 0.558 acre, were laid out. Each plot was divided into 6 sections, divided by a neutral portion into two parts, one of which was electrified while the other served as control.

Owing to the recommendations given by Prof. PRIESTLEY and Mr. JORGENSEN, a screen of wire netting was erected to cut off the charge from the control sections. Tests made showed that the presence of the screen did not entirely prevent the distribution of the discharge over the control plots, especially when the wind blew strongly.

As regards the manuring all the plots were treated equally; as regards the soil it was found that the area of the controls was inferior in quality to that of the electrified area, and this was taken into consideration in considering the results.

The general results obtained in 1917 show that the barley of the electrified plots gave a better yield (an average of 2267 lb. of grain and 29 cwt. 1 qr. of straw) than that of the control plots (an average of 1725 lb. of grain and 24 cwt. of straw); this can only be due to the electrification. Unfortunately this result is not confirmed by the other crops. The potato crop was very good in 1917, and in every case it was heavier on the control than on the electrified areas. The same took place for the hay and oats. The swedes were not included as they suffered from attacks by pests and were blanky. The whole of the turnip crop was uneven in 1917, but so far as the results go the electrified areas have a distinct advantage. It cannot be concluded from the 1917 results that electrification is for some reason specially favourable to barley, for similar results were not obtained in other years.

CONCLUSIONS. — In the experiments at Mains of Luther, the application of a high tension electric discharge on the LODGE NEWMAN system to growing crops have been thoroughly tested over a period of 5 years and no consistent improvement in any of the crops grown — oats, barley, hay, potatoes, turnips and swedes — was obtained. There seems no reason to suppose that electric current applied in this way to growing crops will give results that repay the cost and trouble incurred. Much more scientific work requires to be done to determine the effect of electric discharges on

(1) See "Electricity and Crop Production" by T. H. PRIESTLEY, *Jour. Board of Agr.* 1913. XX, pp. 584-587. (*Author*)

growing plants before we can apply such treatment economically to farm and garden crops or even to decide what kind of apparatus should be used.

Great care is needed in reporting the results of electrocultural experiments so as not to create premature hopes of immediate practical results which, when they are not confirmed, cause disappointment and lead practical men to conclude that science merely leads to useless and wasteful expenditure.

AGRICULTURAL  
BOTANY,  
CHEMISTRY  
AND  
PHYSIOLOGY  
OF PLANTS

1086 — **New Plants and Seeds Introduced into the United States during the Period from January 1 to March 31, 1916** (1). — U. S. Department of Agriculture, Bureau of Plant Industry, Inventory, No. 42 (Nos. 39 682 to 40 388) of Seeds and Plants Imported by the Office of Foreign Seed and Plant Introduction During the Period from January 1 to March 31, 1915, 123 pp. + 9 Plates. Washington, 1918.

Mr. F. N. MEYER undertook a botanical expedition into the province of Kansu, China, and brought back a large number of interesting plants, including the following : —

Some large-fruited wild free-stone peaches (*Amygdalus* spp.) ; the Tangutian bush almond (*Amygdalus tangutica*), very resistant to drought and cold ; a wild pear (*Pyrus ussuriensis*), of the melting juicy type, quite distinct from the hard, gritty ones characteristic of China ; a small vine (*Vitis* sp.) with small bunches of black, edible grapes ; wild, hardy peaches (*Prunus armeniaca*), which may be used for hybridisation work with the aim of extending successful apricot culture further north ; a hardy dwarf crab apple (*Malus* sp.) found at an altitude of 9 000 ft. ; a wild gooseberry (*Ribes alpestre giganteum*), growing to a height of 15 ft., found on dry embankments, a promising hedge plant for the cold, semi-arid districts of the United States ; a very vigorous currant (*Ribes* sp.) found at an altitude of 7 000 ft. growing to a height of 25 ft., a wild cherry (*Prunus setulosa*), a promising stock plant ; Potanin's peach (*Amygdalus persica Potanini*), a bushy plant resembling *A. Davidiana* (so successful as a stock plant) which may prove yet more drought-resistant than this latter ; two wild plums (*Prunus* spp.) from Shensi Province, with possibilities for hybridisation work ; a species of *Citrus* with fruit resembling that of a sour mandarin, which appears to be unusually hardy ; *Populus suaveolens Przewalskii* ; *Daphne tangutica*, an evergreen bush ; *Lonicera* sp., a bush honeysuckle for low hedges in cold districts ; *Schizandra sphenanthera*, an excellent plant for shady beds ; a late-flowering, climbing *Polygonum* ; a new form of Wilson's horse-chestnut (*Aesculus Wilsonii*) from near Chenghsien, Kansu.

The most noteworthy introductions made by correspondants are : — four varieties of maize (*Zea Mays*) from the Valley of Nmaihsa, Upper Burma, where at an altitude of 5 000 to 6 000 ft. there is a remarkable cultivation of maize which appears very ancient ; on one of the varieties were found signs of the characteristic waxy endosperm hitherto only found on maize from eastern China ; a remarkable collection of 27 Spanish maize varieties ; 24 varieties of sweet potato (*Ipomoea Batatas*) from the Station at Santiago de las Vegas, Cuba ; a spineless cactus (*Opuntia* sp.) with very few spicules

(1) See also R., June, 1918, No. 628. (Ed.)

which grow on the dry islands of the Hawaiian group where the Burbank spineless cactus dies rapidly; "mitsuba" or "mitsubajeri" (*Deringa canadensis*) one of the most popular vegetables of Japan; the young leaves are eaten boiled and the roots fried; the Porto Rican black walnut (*Juglans portoricensis*), the nuts of which ripen in April and May; the red bush nut (*Hicksbeachia pinnatifolia*) from New South Wales; late-flowering varieties of English walnut (*Juglans regia*) from Grenoble, France; the Tibetan tree hazel nut (*Corylus chinensis*) which grows to a height of 100 ft.; the small-fruited wild walnut (*Juglans regia*) from Kansu, which is probably very hardy; a new form of Chinese chestnut (*Castanea* sp.) with slender trunk, comparatively resistant to disease; *Pyrus mamorensis* from the Moroccan forests of Mamora, which is resistant to drought and thrives in sandy, non-calcareous soil; 13 varieties of plum (*Prunus bokhariensis*) from Sehaurunpur, India, where they bear fruit from May to the end of June and are adapted to the hotter districts of the United States; the dried fruit of a white mulberry (*Morus alba*) from Afghanistan, where it is largely grown at Kabul; during 8 months of the year these dried fruits form almost the only food of the poor classes there; as Kabul has very cold winters and intensely hot summers, it may be possible to grow this mulberry in Great Plains; the "limoncella" apple from southern Italy considered superior to any variety grown in southern California; a black sapote (*Diospyros ebenaster*) from the Isle of Pines; the durian (*Durio zibethinus*) from Java; a rare species of anona (*Anona scleroderma*) from Guatemala; the Harrar fig (*Ficus* sp.) from Abyssinia, which can stand heavy summer rains and may do well in Texas; the sycamore fig (*Ficus Sycomorus*); the finger citron (*Citrus medica sarcodactylis*) of Japan; numerous shade trees and shrubs for parks and gardens, among which are: — the Egyptian tamarisk (*Tamarix aphylla*) which grows well in reclaimed desert lands where the irrigation water is quite saline; 3 tamarisks from the Caucasus — *T. Hohenackeri*, *T. pentandra* and *T. sp.*; the giant-fruited oak (*Quercus insignis*) (1) from Zacupam, Mexico; *Pittosporum floribundum* and *P. macrophyllum*, from Nice, France; the Guadeloupe Island palm, *Erythea edulis*, possibly suited to the South Atlantic district of the United States; a collection of Japanese flowering cherries (*Prunus serrulata*) from the municipal nursery of Tokyo; the large, wild cherry tree of Japan (*Prunus serrulata sachalinensis*), very hardy and long-lived, sometimes attaining a height of 80 ft., *Tilia euchlora*, a lime the leaves of which are not attacked by insects; *Chaenomeles japonica*, a fine red-flowered quince; *C. lagenaria cathayensis*, the large-fruited Chinese quince, the fruit of which is used in scent making; *Rosa Webbiana* from the Himalayas and *R. sertata* from central China.

1087 — Plant Ecology and its Relation to Agriculture. — WATERMAN, W. G., in *Science*, New Series, Vol. XLVI, No. 1184, pp. 223-228, Lancaster, Pa., September 7, 1917.

The author defines ecology as the *science of organisms as affected by the factors of their environment*; it is connected with both morphology and phy-

(1) See R. 1914, No. 1131. (Ed.)

siology, but more closely with the latter. Up to the present the methods of ecology have been largely descriptive, but now they are becoming increasingly quantitative, employing, in many cases, elaborate and delicate instruments. The experiments are made in the field and in the laboratory under both controlled and natural experimental conditions. The chief aim of ecology and the object of its observations and determinations are to determine the various phenomena observed and to draw from the data obtained the general principles underlying the reaction of plants to their environmental factors.

Plant ecology may be divided into *general ecology* and *special ecology*.

General ecology includes:— 1) *autoecology*, which studies the plant as an individual and is chiefly physiological; 2) *synecology*, which studies the plants in mass and is largely concerned with distribution, and may be regarded as an application of autoecology to the grouping of plants and other organisms within greater or smaller areas of the earth's surface. It may in its turn be divided into *phytogeography*, in which the groupings are regional and result from climatic factors, and *physiographic ecology*, in which the groupings are local, as the result of physiography subordinated to climatic conditions. These different groupings are called *associations*, and the fact that different associations follow each other successively is expressed by the term *succession*.

*Special ecology* of structural groups may, for plants, be subdivided into:—

*Ecology of trees and shrubs*, including the autoecology and the synecology of the group, the influence of the various species on their environment and their classification according to their utilisation.

*Ecology of herbs*, including the study of herbs as distinguished from the preceding group and their classification according to their economic value to man.

*Ecology of the lower types of plants*, with which bacteriology, mycology, etc. are concerned.

Using the word agriculture in a wide sense as denoting the cultivation of the plant products of the soil, its relation to ecology may be studied from the following three points of view:—

**ECOLOGICAL AGRICULTURAL PROCESSES.** — These include:—

1) The formation of optimum conditions:— the preparation of the soil, choice of seed and reproduction material, choice of suitable time and position for the crop; 2) the maintenance of optimum conditions:— the preservation of the moisture and physical and chemical conditions of the soil; the influence of soil temperature; suitable measures for regulating the light, temperature, and wind; control of plant diseases; 3) the harvesting of the crops, where the only function of ecology consists in determining the period most favourable to a maximum yield.

**CONTRIBUTIONS OF ECOLOGY TO AGRICULTURE.** — These may be of two kinds — 1) the development of the principles on which practical agriculture is based; 2) the supply of information for the solution of specific questions and problems bearing on agriculture.

As illustrations of definite contributions of ecology to agriculture may

be quoted the results of research into plant transpiration, and the soil moisture content in relation to the wilting coefficient, and the application of these results to the determination of the amount of water required in irrigation. The study of the extension of the root systems is also important in determining the relation of plants to the moisture content of the soil. No less useful have been the investigations into light, chemical content and plant succession in marshy land. The application of ecological principles in the choice of xerophytic plants for fixing moving sand has also proved of great value.

The difficulties incurred in estimating the measurements of the various ecological factors may be overcome by adopting LIVINGSTON's suggestion of using the living plant as an index instead of carrying out a series of determinations for each separate factor.

Finally the author recommends the introduction into agricultural studies of a course of ecology as a complement to morphology and plant physiology and an introduction to practical agriculture. Whereas the methods followed in practical agriculture, as well as those in agricultural research, are still theoretical, those used in ecology are scientific, although the study material is much the same as that of agriculture, to which ecology would be most largely applied. It is, nevertheless, obvious that ecology belongs to botany as well as to agriculture, and, instead of being a cause of controversy between the two it should be a means of cooperation between both to maintain a high standard in research and generalisation into the conditions under which plants respond to environmental factors.

**1088 - Crop Centres of the United States from an Ecological Point of View.** — WALLER, A. E. (Contribution 99 from the Botanical Laboratory of the Ohio State University, Columbus, Ohio), in the *Journal of the American Society of Agronomy*, Vol. 10, No. 2, pp. 49-83 + 8 Figs. + Bibliography of 25 Publications. Lancaster, Pa., February, 1918.

The geographical distribution of the principal cultivated crops of the United States appears to coincide with the well-known centres of wild vegetation, that is to say, with the districts where the combined action of the climatic and "edaphic" (1) factors form a centre favourable to the development of the species which constitute the local type of vegetation. By comparing the climatic data (chief among which are precipitation and evaporation) and "edaphic" data (dealing with the physical and chemical properties of the soil considered as factors in the distribution of the species) with the distribution of the principal crops of the United States (from information given in a study published by the Department of Agriculture (2) the author confirms the concurrence of the various crop centres of the United States with the centres of wild vegetation.

The maize and winter wheat belts correspond to the central deciduous forest and the prairie centres, the artificial pasture belts to the north-eastern

(1) See R. Dec., 1912, No. 1606. (Ed.).

(2) SMITH M., BAKER, O. E., and HAYWORTH, R. G., *A Graphic Summary of American Agriculture. Yearbook of the U. S. Dept. of Agriculture*, 1915, pp. 329-403 + 4 Diagrams + 38 Maps. Washington, 1916.

evergreen forest, the cotton belt to the south-eastern evergreen forest, the natural pasture or savana belts to the undulating semi-arid districts, unless dry-farming or irrigation have to be reckoned with.

The ratio  $\frac{\text{precipitation}}{\text{temperature of the evaporating surface} \times \text{wind velocity} \times \text{relative humidity}}$ , that is to say, the ratio between precipitation and evaporation, is a useful criterion for marking the limits of the different centres because it is based on factors which greatly influence plant growth. Edaphic factors also frequently determine the distribution of cultivated plants, and, though they may be independent of climatic factors in their effects, often determine the use of the same agricultural methods. The distribution of spring cereals (wheat and oats) is chiefly influenced by edaphic factors. On the other hand economic factors modify the influence of climate and soil, as is especially the case with the potato, the cultivation of which depends largely on soil conditions.

When cultivated crops are grown outside their usual centre their behaviour differs largely from that of the wild plants. The crops are found in the best soils, as only in this case can they compete with the other plants. Many invading plants can, however, only compete with the wild growth in the worst soils; in the better ones the plants of the district have little to fear from invaders. Exotic crops not only demand the best soils but also certain modifications of the soil and, in extreme cases, climatic modifications, i.e., they must be grown under glass or shelter.

Domestic animals are also distributed according to the production centres of the crops upon which they are most dependent. Thus, the dairy industry is concentrated in the artificial pasture belt, the breeding of beef cattle and swine is centred in the maize belt, horse breeding in the oat belt mules are largely found in the cotton belt and sheep in the arid districts,

To sum up, the methods of studying the succession of wild plants can be applied to cultivated crops so long as the conditions produced by the past and present physical factors are definitely determined. The migration of plants, which may lead to their invading another district and competing with and dominating the native plants, is the direct result of the combined action of climate and soil on vegetation. In this connection too much stress cannot be laid on the value of the methods of thorough research used by ecologists in determining the habitat of plants, methods which include the use of instruments for the exact determination of the moisture, temperature, and evaporation, as well as the recording of plant growth in relation to its surroundings by means of photographs.

1089 - A Note on the Analysis and Composition of the Seed of the Silver Maple (*Acer Saccharinum*). — ANDERSON, J. (Chemical Laboratory, New York Agricultural Experiment Station, Geneva), in the *Journal of Biological Chemistry*, Vol. XXXIV, No. 3, pp. 509-513. Baltimore, June, 1918.

In the belief that the seeds, or samara, of the silver maple had never been previously analysed or used as a food, the author made an analysis of them without, however, carrying out digestibility tests.

The samaras dried to constant weight in a current of air at a tempera-

ture of 40 to 50°C. lost 55.34 % of their weight ; 70 % of the dried samara composed the seed properly speaking, the other 30 % composed the wings (pericarp.) The powdered dried seeds, separated from the wings and outer seed coat by rubbing and sifting, gave on analysis the following percentages on a water-free basis :—

**COTYLEDONS.** — Starch 41.94 ; protein ( $N \times 6.25$ ) 27.50 ; sucrose 15.78 ; pentosans 4.07 ; galactan 1.08 ; crude fibre 2.36 ; crude fat, 3.55 ; ash 5.01, containing phosphorus 0.72 ; sulphur 0.16 ; chlorine 0.07 ; calcium 0.09 ; manganese 0.01 ; magnesium 0.18 ; potassium 0.70 ; sodium 0.07.

**PERICARP.** — Dextrose (reducing sugar) 6.11 ; sucrose 0.99 ; galactan 3.45 ; pentosans 15.24 ; starch 14.73 ; crude fibre 34.50 ; crude fat 2.40 ; protein ( $N \times 6.25$ ) 8.15 ; moisture 6.29 ; ash 3.98, containing manganese 0.018 ; sulphur 0.10 ; phosphorus 0.19 ; potassium 0.46 ; sodium 0.08 ; calcium 0.40 ; magnesium 0.10. •

Of the total phosphorus of the ash of the cotyledons (0.72 %) 0.65 % is soluble in 2 % hydrochloric acid (time of extraction = 3 hours) ; 50 % is organic and 15 % inorganic.

The total nitrogen content of the cotyledons is 4.40 %, 0.39 % of which is soluble in 70 % alcohol and 2.06 % in 5 % sodium chloride ; 1.93 % of the total nitrogen remains in residue.

The principal constituents of silver maple seeds are, therefore, starch, protein and sucrose. The principal protein is a globulin. It was found possible to isolate an organic compound of phosphorus very similar to, if not identical with, phytin. As has been seen, the ash is very rich in potassium and phosphorus, the latter being largely derived from the organic compound described above.

#### 1090 — The Chemical Composition of the Loganberry (*Rubus Idaeus Loganii*).

— See No. 1124 of this Review.

#### 1091 — The Chemical Composition of the Pineapple. — See No. 1125 of this Review.

#### 1092 — Stachydrin, a New Nitrogenous Compound Isolated from Alfalfa Hay in the United States.

— STEENBOCK, H. (Laboratory of Agricultural Chemistry, University of Wisconsin), in the *Journal of Biological Chemistry*, Vol. XXXV, No. 1, pp. 1-13. Baltimore, July, 1918.

When analysing alfalfa hay it had been noticed that variations in the histidine and lysine contents determined by different methods in the water soluble nitrogen were attributable to an unidentified nitrogen compound. Considering the importance of each amino-acid in estimating the food value of a ration the author attempted to obtain more complete data on this compound. He successfully isolated from the phospho-tungstic acid fraction of the water-soluble constituents of alfalfa hay a pyrrol derivative, identified in the form of picrate, chlorplatinate, aurate, etc. with the same properties as the compound isolated by VON PLANTA from *Stachys tuberosa* and called by him "stachydrin". It represents one of the many nitrogenous compounds supposed to exist in the water-soluble fraction of foods. Alfalfa hay only contains a small quantity of it, corresponding to 0.5 % of the total nitrogen.

- 1093 — **Discovery of a Cyanogenetic Principle in Toad-flax (*Linaria minor* Desf.).** — GARD, M., in *Comptes rendus de la Société de Biologie*, Vol. LXXXI, No. 12, pp. 621-622; Paris, June, 1918.

In the Scrofulariaceae family, in which hitherto only one species containing hydrocyanic acid was known — *Linaria striata* D. G. (studied by BOURQUELOT, *Journal de Pharmacie et de Chimie*, Ser. VI, Vol. XXX, 1909, Paris) — the author has just discovered that another species *L. minor* Desf. contains a cyanogenetic principle. This plant is very common in Europe, from the Mediterranean district to the north of the continent, except in the arctic zone, and grows in sandy soil. After the cyanogenetic compound had been recognised by the ordinary method — crushing, digestion, distillation and reaction to Prussian blue — it was estimated by LIEBIG-DENIGÉ'S method. It was found that 100 gm. of fresh material contained 0.05832 gm. of hydrocyanic acid, a much higher content than that (0.01478 gm.) found by BOURQUELOT for the other species of this family, *L. striata*.

- 1094 — **Composition of a Plant Salt from the Cameroons.** — LACROIX, A., in *Comptes rendus de l'Académie des Sciences*, Vol. CLXVI, No. 25, pp. 1013-1015 + 3 Tables. Paris, 1918.

It has often been reported that, in African districts where there are no salt deposits and the importation of salt is difficult, the natives use for eating a salt extracted by lixiviation of the ashes of various aquatic or marsh plants (Gramineae, Aroideae, Polygonaceae, ferns, etc., according to the tribe). The first analyses of this salt (DEMOUSSY and DUBOWSKI) showed it to consist mainly of potassium chloride accompanied by variable quantities of sulphates and, sometimes, potassium carbonate. The author analysed a sample of such salt; it was a yellowish-gray in colour and coarse, obtained from a grass which appeared to be a form of *Panicum Crus-Galli*. He found it to contain a certain amount of lime and to be lacking in carbonate, thus differing from all the salts of other localities. A crystallographical examination confirmed the results of the analysis and showed the salts to contain the double salt known as syngenite,  $(\text{SO}_4)_2 \text{Ca K}_2 \text{H}_2\text{O}$ , sylvine, KCl, glaserite,  $\text{K}_2\text{SO}_4$ . In this product of the lixiviation of plant ashes is found, then, the association of the two minerals, sylvine and syngenite which is found in natural salt deposits.

- 1095 — **Relation Between Pigmentation and Oxidation Phenomena in Plants; a Study of the Comparative Respiration of Red Leaves and Green Leaves.** — NICOLAS, G., in *Comptes rendus des Séances de l'Académie des Sciences*, Vol. CLXVII, No. 3, pp. 130-133 + 2 Tables. Paris, 1918.

Numerous investigations have established the relation between pigmentation and oxidation phenomena in plants, but this relation has not been sufficiently supported by experiments on respiration. For this reason the author studied the comparative respiration of: — 1) green leaves and leaves which have turned red accidentally (excessive light, lowering of temperature, fungoid action); 2) leaves which are red when young and turn green as they grow old (*Rosa*, *Cassinia*); 3) green leaves and normally red leaves of the same species (*Prunus cerasifera* and *P. cerasifera* var. *Pissardi*).

The experiments were made by the confined atmosphere method and led to the following conclusions:—

A) **RESPIRATORY INTENSITY.** — In *accidentally* reddened leaves or those red when young and green later, the respiratory intensity is *higher* than in green leaves of the same species, especially with respect to the oxygen absorbed. In *normally* red leaves the respiratory intensity is *lower* than in green leaves of the same species. Red leaves form larger quantities of organic acids than the green leaves; this is expressed by greater oxygen fixation and a decrease in the ratio  $\text{CO}_2 : \text{O}_2$ . There is, therefore, a relation between the formation of organic acids, accompanied by the appearance of the red pigment, and the development of anthocyanin.

B). **RESPIRATORY QUOTIENT.** — In red leaves the respiratory quotient is generally *lower* than in green leaves. Leaves in which anthocyanin has developed consequently fix more oxygen than green leaves. This relation between the formation of anthocyanin and respiratory oxidation is indirect, the oxygen fixed is not connected with the anthocyanin generators, which result from a reduction action (recent research has proved pigmentation to be a reduction, not an oxidation phenomenon). The oxygen acts on other substances, probably the carbohydrates, to form organic acids which are far more abundant in red leaves than in green leaves.

1906 — **Immunity of Plants to the Principles Formed by them.** — COMBES, R., in *Comptes rendus de l'Académie des Sciences*, Vol. CLXVII, No. 7, pp. 275-278 + 2 Figs. Paris, 1918.

Since 1909 the author has conducted bio-chemical investigations into the physiological importance of glucosides in plants (see *Revue Générale de Botanique*, Vol. XXIX, No. 347, p. 321. Paris, 1917). In the course of his work he observed the following facts with regard to the immunity of plants to the principles they form.

Having cultivated several species — corn-cockle (*Agrostemma Githago*) which forms agrostemma-saponin, peas (*Pisum sativum*), buckwheat (*Polygonum Fagopyrum*) and radish (*Raphanus sativus*), which do not form this saponin — in Knop's fluid or in this fluid with the addition of 0.10 to 10 thousandths of the glucoside in question (agrostemma-saponin) he was able to show decisively from the outset that this saponin (even in 0.10/100) is injurious to the roots of plants which do not produce it — peas, buckwheat and radish — but has no injurious effect (even in 10/100) on the plant which forms it — corn-cockle.

The injurious action of the glucoside on the three species which do not form it is seen in the roots, the small, absorbent hairs of which disappear, in the arrest of growth, a loss of dry matter, and, in the pea, by folds on the surface of the root, as is shown by figures given in the paper. On the other hand, corn-cockle cultivated in the presence of the glucoside has shorter, but thicker, roots; the absorbent hairs are also shorter, but in good condition; in fact, there is no sign of disease. It may be concluded that the superficial cells of the corn-cockle root are distinctly immune to the saponin formed and accumulated in its seeds.

Apart from the interest of this fact from the point of view of the immunity of the plant with respect to the products it forms, the author draws

attention to a result of interest as regards physiological technique. When, to study the action of the immediate principles in the vegetable organism, the plant is cultivated in the presence of these principles, it is necessary to use only the species which produces them, otherwise there is danger of drawing false conclusions as to the action of these principles under the natural conditions of the species which forms it.

1097—**Antagonism Between Growth and Reproduction in Plants; Factors Influencing these Two Processes.**—BLACKMAN, V. H. (Imperial College of Science and Technology, London), in *Science Progress*, Vol. XIII, No. 49, pp. 49-53. London, July, 1918.

It is well known that in many plants there is a marked antagonism between growth and reproduction. In such cases (especially in fruit trees), the reduction of vegetative growth, e.g. by root pruning, causes vigorous reproduction. The study of the factors influencing these two processes is, therefore, of great importance. In higher plants, however, it presents great difficulties because of the close connection between the various external factors, none of which can be artificially modified without modifying others at the same time. It is, therefore, necessary to use lower species, algae and fungi, the cultivation *in vitro* of which presents little difficulty and may be made under conditions easy to modify. The facility with which such cultures may be made has led to neglect largely the study of the intervening features, such as temperature, aeration, etc., and the attention of workers has been concentrated especially on the composition of the media (PASIEUR, RAULIN, WINOGRADSKY, BEIJERINCK). One of the first workers to study the influence of external factors on pure cultures of algae and fungi, KLEBS, showed that growth and reproduction are dependent on certain of these factors, and that, in the presence of factors favourable to growth, reproduction does not occur. He also showed that the factors favourable to reproduction are more restricted than those favouring growth. KLEBS' theory has been confirmed by investigations into the biology of a fungus, *Plenodomus fuscomaculans*, made by COONS (*Journal of Agricultural Research*, Vol. V, No. 16 pp. 713-769, 1916) (1). These investigations showed, amongst other things, that light is an essential factor for reproduction, but that it may be replaced by a few drops of hydrogen peroxide or other oxidising agents. This fact suggested the hypothesis that there exists between the parts of an organism a strong competition for oxygen, and that in the presence of factors favourable to growth all the oxygen is used for metabolic processes. Under the influence of light or an oxidising agent, oxidation of the richer cell materials takes place, liberating a certain amount of energy, which changes the reserve food stuffs into complex protein bodies, the spores.

PLANT  
BREEDING

1098—**The Heredity of Early and Late Ripening in an Oat Cross, in England.**—ST. CLAIR CAPOIN, A., in the *Journal of Genetics*, Vol. 7, No. 4, pp. 247-257 + 1 Fig. Cambridge, August, 1918.

The results are given of experiments in the inheritance of earliness by crossing the early oat, Mesdag (ripe on July 26 in 1913) and the late oat Hopetown (ripe on August 13 in 1913).

(1) For abstract of this paper: see R. May, 1916, No. 572. (*Ed.*)

In spite of the relatively long ripening stage (from the appearance of the first panicles till all the panicles are completely ripe) there is no overlapping of the phases of the two varieties, in fact there is always a distinct gap between them as Mesdag is always completely ripe before any of the Hopetown panicles are ready for harvesting. The observations made from three generations of hybrids are given below.

*F* Generation. — Hybrids with long, strong awns, brown grains (like the parent Mesdag), compact panicles (like the parent Hopetown), ripening a little before the late parent and a little after the early one. They, therefore, had characters intermediate to those of the parents with a tendency on the part of Mesdag to dominate.

*F*<sub>2</sub> Generation. — As all the plants were harvested at the same time the results were not very definite or certain. Nevertheless, a careful examination showed the presence of:— 1) early forms (like Mesdag); 2) late forms (like Hopetown); 3) intermediate forms.

*F*<sub>3</sub> Generation. — Grains from 106 panicles chosen from *F*<sub>2</sub> were sown in separate rows; there was also a row for grains from each of the parents. From the beginning of the ripening period the number of ripe plants in each row was noted daily. Plants were called ripe when the last trace of green had disappeared from the tips of the paleae. The data thus obtained made it possible to calculate with exactitude the earliness of each row. An examination of the table in which these data are set out shows the following facts:—

1) Mesdag : ripening period from August 10 to 24.

2) Hopetown : ripening period from September 4 to 21.

There was, therefore, an interval of ten days between the ripening periods of these two parents.

3) In the *F*<sub>3</sub> hybrids there were forms intermediate to the two parents.

4) In no row were there plants as late as Hopetown.

5) In no row were there plants as early as Mesdag.

Nevertheless, in two rows (Nos. 17 and 97) the delay was very slight (2 to 3 days), so that their earliness might be considered practically equal to that of Mesdag. The two rows out of a total of 106, gave the ratio 1 : 63.

6) In 24 rows the ripening period extended over the ten-day interval between the ripening periods of the two parents, *i. e.*, was not ended on September 4 when the first ripe panicles appeared on Hopetown. The number 24 is very close to the theoretical number 26.5 ( $106/4$ ) corresponding to the ratio 1 : 3.

CONCLUSIONS. — The results obtained seem to show that early and late ripening are Mendelian characters depending on more than one factor; perhaps three *F*<sub>2</sub> plants homozygous for one of these factors are early in the sense that their *F*<sub>3</sub> descendants are completely ripe before any plant of the late parent. On the other hand, only homozygosis of the three factors can produce earliness equal to that of the early parent. The various combinations of these factors, their absence or their presence in the homozygous or heterozygous state, explain all the intermediate conditions.

**1099 — Selection of Maize Resistant to Smut (*Ustilago Zeae* Beck), in the United States.** — JONES, D. F., in the *American Journal of Botany*, Vol. V, No. 6, pp. 295-300 + Bibliography of 19 Publications. Lancaster, Pa., June, 1918.

For these selection and hybridisation experiments, made to study the inheritance of resistance to smut in maize, were used 16 strains of this cereal which had been self-fertilised for from 9 to 11 generations. At the beginning the progeny showed little uniformity, but this gradually increased till finally the homozygous state appeared to be attained and the various groups or types remained constant.

The strains thus obtained showed degrees of resistance to attack from smut varying between a minimum of 9.79 % of the plants from strain 1-7-1-1 and a maximum of 0 % for the strain 1-6-1-3, which may be considered as practically immune to the parasite. The vigorous development of the plants of this strain must not be considered as the chief cause of resistance because other highly immune strains develop only moderately.

By crossing a susceptible with a resistant type almost completely immune plants were obtained in  $F_1$ , whereas in  $F_2$  there were susceptible plants in a ratio agreeing with the laws of scission and re-combination of characters, although want of material has not yet made it possible to obtain definite data.

The results seem to show conclusively that susceptibility to smut is governed by special determinants or genetic factors and may be modified by suitable selection.

**1100 — Observations on some Degenerate Strains of Potatoes.** — STEWART, F. C., in the *New York Agricultural Experiment Station, Bulletin* No. 422, pp. 319-357 + 12 Plates. Geneva, N. Y., July, 1916.

The results are given of investigations made by the author in the experiment fields of the New York Agricultural Station at Geneva to determine the manner in which the potato diseases known as leaf-curl, curly dwarf, mosaic and spindling-sprout are transmitted from one generation to another. These seem to be less diseases properly speaking than forms of degeneracy, for in no case was it found possible to isolate pathogenic micro-organisms. The action of the soil and weather factors must also be excluded.

The two principle results obtained showed that :

1) The tubers of affected plants nearly always produce more or less degenerate and useless plants. In 1914 were chosen 47 badly affected specimens, from which were obtained, in 1915, 197 plants, all diseased with the exception of one (of the Ionia variety).

2) Perfectly normal plants (Pride of Vermont, Green Mountain, etc.) may produce degenerate types. Tubers of the same plant, and even different eyes from one and the same tuber, may produce both normal and abnormal plants.

This last fact, as well as the constant transmission of the degenerate types, seems to show that these hereditary diseases may be produced as real mutations or bud variations. This is born out by the rapid degeneration frequently observed in the descendants of perfectly healthy plants. For example, a tuber of the Green Mountain variety planted in 1913 gave

63 seed-pieces for the following year; all the plants produced from these pieces were healthy and perfectly normal. The tubers of 36 of these plants were planted in the spring of 1915 in three plots in three different localities, Riverhead (Long Island), Cadyville (New York), and Presque Isle (Maine), and produced in all three places many decidedly degenerate plants.

CONCLUSIONS. — 1) Tubers from plants affected with leaf-roll, curly-leaf and mosaic transmit these degenerate characters to their descendants. All tubers from plants which are even only slightly abnormal should, therefore, be eliminated.

2) Degenerate forms crop up unexpectedly as mutations from material which has been perfectly healthy for several generations, so that even a very careful sorting of seed tubers will not exclude the possible occurrence of abnormal descendants subject to degeneration.

1101 — **Deli-Tobacco with Petiolate Leaves. Probably Resulting from Mutation of a Single Factor, at Sumatra.** — HONING, J. A., in I. *Bulletin van het Deli Proefstation*, No. 10, pp. 1-24 + 5 Tables + 6 Figures, Medan (Sumatra), October, 1917; II. *Mededeelingen van het Deli Proefstation*, Year X, Pt. 8, pp. 185-189 + 6 Figs. Medan, December, 1917.

Now and again (once in 100 million times, or still less) Deli tobacco, which normally has sessile leaves, produces plants with leaves having a long petiole and also differing from the normal type by: — cross lines (1), a zigzag stalk, small, losenge-shaped leaves with small appendices on the under side ("Kroeppek") (2), sometimes growths on the corolla.

In 1914, in the plantation of Foentoengan (Sumatra), was found a Deli tobacco plant with petiolate leaves. It was self-fertilised and in the  $F_1$  gave 2896 plants which were divided into three different types: — a) 704 (about  $\frac{1}{4}$ ) of the normal Deli types; b) 1446 (about half) hybrid plants with leaves with petioles which were at first short but later grew till they were of the same length as those of the parent plant; c) 746 (about  $\frac{1}{4}$ ) sterile dwarf plants with irregular leaves, which first had a long petiole but subsequently lost the blade, so as to assume a linear form. The segregation, therefore, was in the Mendelian ratio of  $\frac{1}{4}$ :  $\frac{1}{2}$ :  $\frac{1}{4}$ , or 1: 2: 1, showing the parent plant to be a heterozygous hybrid with respect to a single factor (Aa).

Nine of these  $F_1$  hybrid plants on self-sterilisation gave an  $F_2$  including 4655 plants of which 1155 were normal, 2392 hybrids, and 1108 abnormal (dwarf), i. e., always in the ratio 1: 2: 1.

On the other hand reciprocal crosses between hybrid and normal plants of  $F_1$  gave normal and hybrid plants in the ratio 1: 1.

Finally, the normal plants (Deli type) of the  $F_1$  when self-fertilised instead of giving exclusively normal descendants gave, in two cases, a number of abnormal plants — 3 hybrids and 2 dwarfs out of a total of 764. This phenomenon is as mysterious as the origin of the plant with petiolate leaves of Foentoengan.

(1) The author calls thus the pale green lines placed, in the variety of tobacco with non-decurrent leaves, in the positions corresponding to the insertion of decurrent leaves in the varieties with normal leaves.

(2) See R. 1914, No. 288. (Ed.)

It is most improbable that this plant was derived from an accidental cross between Deli tobacco and the native tobacco with petiolate leaves because the characters of the Deli type reappear without variation in the  $F_1$  and other abnormal types, both homozygous and hybrid, resembling none of the tobaccos cultivated by the natives of Malaya and Batak.

The author explains the origin of this curious plant as follows — a germ cell of the Deli type was fertilised by a cell having but one changed factor, *i. e.*, having undergone *mutation* for one factor only (whereas DE VRIES considers the oöules of *Oenothera Lamarckiana* to have undergone mutation for several factors). In support of this hypothesis he calls to mind that a *single* factor may produce *several* effects, as has been shown by LODEWIJKS for tobacco (*Erblichkeitsversuche mit Tabak*, in *Zeitschrift für induktive Abstammungs- und Vererbungslehre*, Vol. V, p. 144, 1911) and MORGAN for other plants (*The Mechanism of Mendelian Heredity*, p. 35, 1915).

#### AGRICULTURAL SEEDS

**1102 — Variations in Seed Tests Resulting from Errors in Sampling.** — STEVENS, O. A., in the *Journal of the American Society of Agronomy*, Vol. X, No. 1, pp. 1-19 + 12 Tables + 3 Figs. Lancaster, Pa., January, 1918.

Variations in the results of seed testing are largely unavoidable. They may be divided into two groups, one purely mathematical, the other personal or, to a large extent, economic (due to lack of money to buy the best apparatus and to employ efficient and trained workers). The direct mathematical causes are:—

*For germination tests:*— imperfect mixing, random sampling, errors in counting, effect of personal selection (there is a tendency to pick out the better seeds), unsuitable conditions for germination, special condition of the seed.

*For purity tests:*— imperfect mixing, random sampling, errors in weighing, effect of personal selection, errors of identification.

During the years 1914 and 1915 the author investigated in the Department of Botany of the North Dakota Agricultural College the errors due to mathematical causes. Both in the germination and purity tests the general plan was for one person to take simultaneously a series of 50 tests from one lot of seed and to calculate the standard deviation and probable error.

**GERMINATION TESTS.** — A white-seeded kafir was chosen as experimental material. Part of the seed was stained red with an alcoholic solution of Delafield's haematoxylin to represent dead seed.

I. — To determine the amount of mixing required in a sample received by an analyst, 55 grams of white seed and 55 grams of stained seed were placed together and poured from one dish to another at the rate of 50 times per minute. This process was repeated 25, 75 and 200 times, and the whole series then duplicated. The probable error was respectively 3.10, 2.88, and 2.83 for the first series, and 3.05, 2.83, and 2.82 for the second series. This remarkable agreement shows that very little difference results from mixing beyond a certain limit. (In all the tests described the seed was mixed 75 times. To choose the sample to be tested the mixture was poured

on to the table, the pile drawn out to a point at one end by placing a hand on either side, and 100 seeds counted.

II. — The second problem was to determine the error for a given percentage. Theoretically a sample containing 100 % of live seed should give no variations in the various tests; a sample with 90 % live and 10 % dead seed should give the same variations as one with 10 % live and 90 % dead seed, and so on, till the maximum variation is obtained with 50 % of each type. When a test sample also contains hard seed the variation will be greatest when all three kinds of seed are present in equal proportions. The probable error for such a sample was found to be 3.83, 3.92, and 3.01 for the live, dead, and hard seeds respectively.

The author gives in a table the probable errors in the percentage of live, dead, and hard seeds determined by him from mixtures containing 50, 60, 70, 80, 90, 95, 97, and 99 % of viable seed, in which (with the exception of the three last) the rest of the percentage was composed of: a) 5 % of dead seed, the remainder being hard seed; b) 10 % of dead seed, the remainder being hard. In another comparative table are given the results of four lots of seed (alfalfa, millet, bromus and red clover) tested in about 20 different laboratories, the probable error being calculated in lots of 100 seeds.

III. — The above figures were obtained for samples of 100 seeds. The limits of error were also investigated for samples containing a number of seeds equal to multiples of 100 or less than 100. For this purpose tests were made with several series of 200 tests with millet, alfalfa, flax, and kafir seed, each lot of 50 being made separately. The results were calculated for each set of 50 tests, for each set of 50 obtained by taking the mean of the first and second, third and fourth, and by taking the mean of each set of three and of four tests. Series based on 100, 200, 300, and 400 seeds were thus obtained the results of which are given in a table. For example, a mixture of alfalfa with an 83.0 % germination (9 % hard seeds) gave the following probable errors:— for the four series of 100 seed tests, 2.49, 2.62, 2.48, 3.02; for the two 200 seed tests, 3.01, 2.27; for the 300 seed test, 1.82, and for the 400 seed test 1.43. A mixture was also prepared containing 80 % of viable seed and a series of 500 lots of 100 seed each was counted in distinct groups or in combinations as in the previous case, and tests made using 100, 200, 300, 400, 500, and 1 000 seeds, with the following results:— for 100 seeds the probable error was 2.65; for 200 seeds, 1.78; for 300, 1.50; for 400, 1.35; for 500, 1.25; for 1 000, 0.85 %. When less than 100 seeds were used the error was considerably increased. A trial with 50 % of live and 50 % of dead seed made with 50 lots of 50 and 25 seeds each, gave probable errors of 4.26 and 6.73 % respectively.

IV. — If the results of two tests of one sample vary rather widely is the mean of the two further from the mean of the series than when the variation between the two tests is less? In other words, is it necessary to make a new test when the variation between two tests exceeds a certain quantity?

To solve this problem the alfalfa series and kafir (60 % germination; 32 % hard) from the previous experiment and the 80 % kafir series were

used. The mean of each successive pair (1st. and 2nd.; 3rd. and 4th., etc.) was calculated, and the deviation of these means from the mean of the whole series of 200 found. In the alfalfa series 17 % of the duplicate tests showed a variation exceeding 10 %, their average deviation being 4.15 % (12 exceeded the probable error). The average deviation of the other 83 was 3.44 %. On the other hand, there was in one case 1 % difference only in the duplicate tests, the mean of the duplicates differing from the mean of the series by 9 %. Among the duplicate tests differing by 2 % only, two differed from the mean of the series by 6.5 %, and one by 5.5 %, etc. Of the 100 duplicates of the 60 % kafir series, 9 showed a difference exceeding 10 % of the mean of the two tests, and the mean of the entire series. The average deviation of the means of these 9 from the mean of the whole series was 2.44 %; that of the other 91, 2.97 %. In only 4 of the 9 did this deviation exceed the probable error of 2.2 %. In the 80 % kafir series 46 of the 250 duplicates showed a difference of over 8 %. The average deviation of the means of these 46 from the means of the whole series was 2.35 %, whereas in the other 204 cases it was 2.06 %. Only in 24 of the 46 cases did the deviation exceed 2 % (the probable error in tests of 200 seeds is 1.87 %). It is, therefore, clear that in such a case wide variations between duplicate lots does not appreciably reduce the accuracy of the results.

By the rule of the Official Seed Analysts of North America re-tests must be made when the variation between duplicates of 100 seeds exceeds 6, 7, 8, 9 and 10 % for a germination of 90 % or more, 80 to 90, 70 to 80, 60 to 70, and 50 to 60 % respectively. The author's results show this regulation to be of doubtful value, because the variation may be greater without destroying the value of the test, or it may be smaller and the exactitude of the result doubtful.

VARIATIONS IN PURITY TESTS. — These may be due to many factors since each of the three chief components of the sample (pure seed, foreign seed, inert matter) may have a variable number of components for which it is difficult to find a value of accuracy for use in a large series of cases.

The seed used did not show any unusual variations. In taking the samples a seed mixer and sampler such as adopted by the U. S. Department of Agriculture were used. Determinations were made of: — *a*) the probable error in purity tests of flax (2 lots), alfalfa, and brome grass; *b*) the value of the second decimal (as compared with only one decimal figure) in calculating the probable error; *c*) the variation in the number of foreign seeds in a given species; *d*) variations due to personal selection.

CONCLUSIONS AND RECOMMENDATIONS. — I. The probable error of a single germination test of 100 to 400 seeds for percentages of germination of 99, 97, 95, 90, 80 to 50 respectively varies as follows: — 0.75, 1.00, 1.50, 2.25, 2.80 in samples of 100 seeds; 0.50, 0.70, 1.00, 1.50, 2.00 for 200 seeds; 0.40, 0.55, 0.80, 1.20, 1.75, for 300 seeds; 0.35, 0.50, 0.70, 1.05, 1.50 for 400 seeds. The figures increase by about  $\frac{1}{5}$  in the lower percentages of germination for Leguminosae containing so-called "hard" seeds. This is for work in which the causes of variation are reduced to a minimum. No

attempt was made in this study to determine the range of value when factors other than those of mathematical probability enter to any extent. These values may be used for other experiments involving similar conditions, e. g. in counting 500 seeds to determine the percentage of mixture of two kinds.

II. — In samples which do not contain mixtures of materials with a tendency to separate readily (such as sand, fine impurities, or coarse material) only a small amount of mixing seems necessary. Such samples should receive a supplementary test of larger quantity to show the approximate amount of such materials. For example, these may be first separated by a sieve, and the percentage added to that obtained by a regular test from the remaining quantity.

III. — The accuracy of purity tests depends on many factors. The quantities used should be carefully investigated to determine whether those in current use may be advantageously changed. The second decimal figure is of no value in most cases. If such accuracy is required the determination must be made with a sufficiently large sample (e. g. for about 8 oz. of wheat 30 gm. should be taken; for flax and small seeds, three times the usual quantity).

IV. — Results of seed tests should be accompanied by an indication of their accuracy, *i. e.*, by the value of the probable error. In practical tests this should be doubled because there are about four chances in five that the correct result lies within the figure thus corrected.

V. — The second decimal figure is not necessary for the calculation of the probable error in such tests.

VI. — The amount of seed used for such tests (and therefore the degree of accuracy obtained) should be regulated by two factors — the degree of accuracy required for dependable results, and the amount of work it is possible to handle. In germination tests it is advisable to use 200 seeds per test, the number being increased if desired. It is most important to know the probable error so that such adjustments may be made.

VII. — Duplicate tests appear to be of little value; one test of 200 seeds will often require less space and time than two of 100 seeds.

The author compares his results with those of RODEWALD (*Über die Fehler der Keimprüfungen, Landwirtschaftliche Versuchsstationen*, Vol. XXXVI, pp. 105-112, 215-227; 1899), with which, on the whole, they agree well.

1103 — **Date and Rate-of-Seeding Tests with Spring Grains under Irrigation.** — ATKINSON, A., in the *University of Montana, Agricultural Experiment Station Bulletin* No. 120, pp. 107-117 + 15 Tables. Bozeman, October, 1917.

CEREAL  
AND PULSE  
CROPS

The experiments described were carried out at the Montana Experiment Station farm at Bozeman, in the Gallatin Valley in the south-central part of the State, at an altitude of 4870 ft. The plots were  $\frac{1}{40}$  acre in size. The tests were made with the principal varieties of cereals, sown in lines with a seed drill carefully calibrated to control the exact quantity of seed sown. The influence of different dates and rates of sowing on the yields of grain and straw, the weight of grain per bushel, the length of the period from planting to ripening, the height of the crop, and the percentage

of the crop lodged at harvest time, were carefully observed. The tests were made during 8 years for spring wheat, oats, and barley, and during 7 years for peas. The principal results obtained are given below : —

**DATE OF SOWING.** — The largest yield of grain was obtained with the earliest sowing. Yield from plants sown on April 15, 22, 29 and May 5, when compared with those from plants sown on May 13, 20, 27 and June 4, showed an average increase, in favour of early sowing, of 44.6 % for spring wheat, 19.1 % for oats, 11.7 % for barley, and 10.6 % for peas. There were but slight differences in the quantity of straw produced according to the date of sowing. Since late planting gave smaller yields of grain, the number of pounds of straw for each pound of grain produced was greater for crops sown late than for those sown early.

Early sown grain was of better quality than late sown grain, as shown by a higher average weight per bushel. The vegetative period of early sown grain was longer than that of late sown grain. This was doubtless due to the fact that the growth of plants sown late was arrested by autumn frosts and cool weather.

There was no marked difference in the length of straw of the plants sown at different dates. This is in agreement with the essentially uniform yields of straw. Lodging of cereals depends more on the season than the date of sowing.

**RATE OF SEEDING.** — The highest yield of spring wheat was obtained by sowing 14 pecks per acre. This was 2.6 bushels higher than the yield obtained with 8 pecks. Considering the higher price of grain in the spring, the most profitable yield was from 8 peck seeding. The best yields of oats were obtained with 10 to 12 pecks of seed per acre. Sowing 16 pecks per acre gave the best yields of barley. When other conditions, such as lodging, were considered, the best yields were obtained with 8 to 10 pecks of seed. For peas, the most satisfactory results were obtained with 10 to 12 pecks per acre.

The yield of straw increased in proportion to the amount of seed used.

The quality of the grain as shown by the weight per bushel was slightly better for spring wheat, oats, and barley when larger quantities of seed were used. With peas the opposite was true. The larger the amount of seed used the shorter was the period from sowing to ripening. The amount of seed used should, therefore, be increased in proportion as the date of sowing is retarded in spring.

There appears to be no relation between the length of straw and the amount of seed sown in the case of spring wheat, oats, and barley. For peas, the length of the straw increased as the quantity of seed used increased. The higher the rate of seeding the greater was the tendency of the crop to lodge. It must be remembered that these data refer to irrigated crops at an altitude of 4870 ft.

**1104 — Comparative Cultural Experiments with Several Varieties of Oats in South and Central Sweden.** — AKERMANN, A., in *Sveriges Utsädeförenings Tidskrift*, Year XXVII, Pt. 6, pp. 261-278; Year XXVIII, Pt. 1, pp. 26-25. Malmö, 1918.

During the last 20 years the Svalöf station, aided by the various bran-

ches distributed throughout the different physiographical districts of Sweden, has created and tested several new and valuable varieties of oats which have replaced, or are replacing, the old native varieties which they exceed in quantity and quality of yield. As is known, the yield of a given variety varies from year to year according to the different weather conditions. To determine the climate of a given locality it is necessary to make a series of observations over several years, and to determine the productivity of a given variety with respect to the climate it is also necessary to make comparative cultural tests for a more or less long period.

Among the oats produced at Svalöf are the varieties Kron, Seger, Guldregn, Stormogul, Klock I, II, and III, selected Dala, and others. Comparative cultural experiments made on several farms in south and central Sweden have made possible good approximate determinations of the characters of these varieties with respect to the special climatic and agricultural conditions of the different provinces, thus enabling a geographical distribution to be made on a rational and reliable basis. The comparative cultural tests may be divided into four parts:—

- 1) Tests at Svalöf, from 1900 to 1917.
- 2) Tests in the provinces of southern Sweden (white oats district) from 1908 to 1917.
- 3) Tests in Värmland, from 1908 to 1916.
- 4) Tests of varying length in the provinces of central Sweden (black oats district).

I. SVALÖF (1900-1917). — Beginning with the Kron variety, which occupies the first place, the other varieties come in the following order of merit:— Gule Näsgård, Banner, Strubes Schlanstedter, Tystofte Stjern, Seger, Guldregn, Klock III, common Probsteier, beardless Probsteier, Stormogul, Ligowo, and Klock II. An examination of the weather conditions shows the well-marked positive action of rain during the vegetative period, from May 1 to August 15 in years when the total rainfall during this period is 200 mm. or more, especially if the rain is not only abundant, but also well distributed. When, however, this total is below 150 mm., as in 1914 (127 mm.) and 1917 (88 mm.), the yield in grain is  $\frac{1}{3}$  or more below the average. All the varieties are not equally sensitive to weather conditions, with the exception of those generally known to be favourable or unfavourable. Thus, in dry years, the Guldregn variety, which is very resistant, gives better results than Seger oats and, under the same conditions, the black oats Klock and Stormogul can compete with, and even excel, the best white oats. In 1917, for example, the first place was held by Stormogul with  $28\frac{3}{4}$  cwt. per acre, followed by the varieties Guldregn, Gul Näsgård, common Probsteier, Klock III, Seger, Kron, and Klock II. The choice of any variety must depend on the most unfavourable weather factor of the district in which it is to be grown.

II. SOUTH SWEDEN (1908-1917). — Of the white oats, the Seger variety holds first place in the provinces of Malmöhus (25.97 cwt. per acre), Kristianstad (23.29 cwt.), Södra Kolmar (22.17 cwt.), and Skaraborg (21.98 cwt.), but in this last province Stormogul black oats surpass all white oats.

The Kron variety does best in the provinces of Halland (23.62 cwt.) and Älfsborg (24.38 cwt.), whereas the Guldregn variety gives better results than Seger in one case only, in the province of Kronoberg (19.42 cwt.), where the unfavourable climatic conditions emphasise the properties of earliness and drought resistance peculiar to Guldregn.

III. VÄRMLAND. — Although included in the white oats district, this region must be considered separately. Two conditions deserve attention:— 1) the late spring which makes it necessary to sow 8 days later than in the Uppland; 2) the drought of June, especially in the southern parts and in the Dalsand (northern part). Thus, at Karlstad, the June rainfall does not exceed 46.5 mm., whereas at Nora it is 65.1 mm., at Falun 55.8 mm., at Örebro 55.4 mm., at Skara 51.1 mm. and at Vänersborg 57.9 mm. This shows the necessity of drought resistant and very early types. Among the white oats the Guldregn variety holds first place (15.71 cwt.) excelling both the Seger (15.07 cwt.) and Dala (14.77 cwt.) varieties, but it is decidedly inferior to the Stormogul (17.25 cwt.) and Klock II (16.26 cwt.) black oats.

IV. CENTRAL SWEDEN (1909-1916). — The black oats district includes the province of Östergötland and parts of those of Småland and Närke, as well as the provinces on both sides of Mälaren (Södermanland and Uppland).

*Östergötland.* — The Klock III variety, obtained by NILSSON by crossing Klock II with Stormogul, gave results (21.08 cwt.) so much superior to those obtained with the parent plants that it could safely be grown in the place of Klock II (18.71 cwt.).

Stormogul leads for yield in straw (42.11 cwt.), and by completely uprooting all *Berberis* it was possible to eliminate *Puccinia graminis*, so injurious to Stormogul which, in yield can compete with Klock III. The Fyris variety gave results superior to the parent variety Roslag.

*Mälaren provinces.* — Of all the varieties examined Stormogul gave the best results, both in heavy clay soils and in light sandy soils. Only in the northern parts of this district was it necessary, on account of its late ripening, to limit Stormogul to the fertile soil zone so as to favour rapid growth of the plant.

Klock III shows very good promise although there are not sufficient data available to establish with precision the district to which it is best suited.

On the whole the Fyris variety has given less satisfactory results than Klock, but in some very clayey parts of Mälaren and large tracts of Uppland this variety is to be preferred to all the other black oats on account of its earliness. From a point of view of quality of grain and tillering Fyris should prove of excellent use in selection and hybridisation experiments in the clay soils of central Sweden.

1106 — The Control of Weeds in Ricefields by Rolling. — TARCHETTI, A., in *I Giornale di Riscoltura (Organo Mensile della R. Stazione Sperimentale di Riscoltura e delle Coltivazioni Irrigue, Vercelli)*, Year VIII, No. 4, pp. 51-58 + 2 Figs. Vercelli, April 30, 1918.

Although most farmers no longer use rolling as a means for keeping down weeds in ricefields — and the author thinks they were wrong in

abandoning the practice — many well-known practical men still use it on a large scale and repeat it each year with increasing success.

Rolling is specially successful in first-year ricefields and in these with numerous sedges; it should be abandoned for grasses. The corrugated roller (with wooden laths or iron bars  $1\frac{1}{2}$  in. sq.) should be used. The best time for rolling is when the sedges have grown as tall as the rice; during rolling sufficient water should be maintained in the ricefield so as to prevent the roller burying the rice plants in the soil so that they cannot grow up again. The trampling of the plants by the team and the difficulty of turning are two disadvantages that should be avoided or diminished. To this end, the suggestion has been made to make rollers with 2 or 3 sections with a total length of 10 to 13 ft. so that the land between two irrigation ditches could be rolled in 2 turns — going and coming; but this roller requires 2 horses instead of one and the trampling would be great.

The author suggests the use of a roller with 2 sections loose on an iron axle equal to the width of the land, so that the sections could be spaced as required on the axle. The swingle-tree for 1 horse is attached to the middle of the axle.

With a land twice the width of the roller, the 2 sections are moved towards the centre of the axle as shown at *A* in the figure, and the horse (2 horses may be used) walks in the ditch *CD*, thus rolling on both sides of the ditch. When at *D*, the apparatus is turned, the horse passing in the ditch *EF*, as shown at *A<sub>1</sub>*, and so on for the other trenches. When the first rolling is finished, the 2 sections are moved to the position *B*, and the operation is finished without ever trampling the young plant, save on the headlands. The headlands would be rolled last of all, so as to flatten out the hoof marks.

The use of a roller with 2 sections loose on the axle in a rice field.

CROPS  
YIELDING OILS,  
DYES AND  
TANNINS

1111 - Olive-Growing in Australia. — *Queensland Agricultural Journal*, Vol. 9, No. 1, pp. 18-20 + 1 Fig. Brisbane, January, 1918.

Before the war olive trees had never been grown on a commercial scale in Australia. As present supply difficulties on the European markets have stopped the importation of olive oil to Australia, the growing of olives is attracting much attention there.

South Australia may be said to be the only State producing olives. The total area of the olive orchards there only amounts to 1000 acres with an annual production of oil of about 15 000 gallons. The variety of conditions under which olive trees do well makes it certain that more extensive cultivation of them would succeed. Prof. PERKINS believes that the olive orchards could be extended to 15 000 or 20 000 acres, especially in districts with a light rainfall where the soil contains sufficient lime. The soil and climate of Queensland are just as well suited to olive growing as those of South Australia.

Mr. BURING, who has grown olives for many years, believes that the labour difficulties which olive growing on a commercial scale would encounter make it necessary to restrict the cultivation of this fruit to small orchards but that this should be general. In other words, he recommends all those who have orchards to reserve one plot for olives. He gives the Verdale variety preference over all others because, though its oil content is not very high in proportion to the weight of its fruit, it is the most resistant variety, thriving on the coast as well as inland, at sea level as well as at altitudes of 4 000 to 5 000 ft., and resisting very low temperatures.

It is usually assumed that olive trees do not come into bearing for several years. The use of fertiliser and good irrigation will, however, reduce this period and make it possible to obtain a crop four years after planting out.

1114 - The extraction of Berberine from "Michai" (*Barberis Darwinii*) and "Calafate" (*B. buxifolia*), in the Argentine. — RICHERT, F., in *Revista del Centro Estudiantes de Agronomía y Veterinaria de la Universidad de Buenos Aires*, Year XL, Nos. 92-93, pp. 11-13. Buenos Aires, January-May, 1978

"Michai" and "calafate" grow largely in the Patagonian Cordilleras. By extracting the powdered roots with hot water are obtained large quantities of berberine, a yellow colouring substance which fast dyes animal fibres without previous treatment with mordants. The natives use these aqueous extracts for dyeing mats, etc.

An experimental study made at the "Instituto quimico de Investigaciones agropecuarias" showed the dry powder of "michai" root to give 8.9% of crystallised berberine after extraction with hot alcohol, precipitation with ether and evaporation of the precipitate. The treatment of "calafate" roots is not so simple because the berberine in them is accompanied by other crystallisable compounds which are extracted simultaneously. In this case it is necessary to acidify the alcohol extract with dilute nitric acid. By these means 3.5 to 4% of crystallisable berberine nitrate is obtained.

1116 - Experiments with Hevea in the Dutch East-Indies. — I. ARENS, P. E. (Proefstation Malang), Eenige aan de praktijk ontleende cijfers omtrent den invloed van het uitdunnen op de productie van Hevea-tinnen. *Archief voor de Rubbercultuur in Nederlandsch-Indië*, Vol. I, No. 4, pp. 234-240. Batavia, 1917. — II. BISHOP, O. F., GRANTHAM, J. and KNAPP, M. B. (Technical Department, Holland American Rubber Company), Probable Error in Field Experimentation with Hevea. *Ibid.*, No. 5, pp. 335-362.

I. — In the first paper figures are given as to the effect of thinning out Hevea fields on the rubber-yield per acre.

In the first case, in three fields planted 12' × 24' one alternate row was taken away in the course of one month thus bringing the distance to 24' × 24'. Though half the trees were removed the yield of these fields did not show any decrease. The average production per field and per tapping-day during the three months preceding thinning out had been 4.28 lb. and that during the three months following thinning out 4.12 lb., whilst the figures for the three control-fields for the same periods were 3.33 lb. and 3.17 lb. The decrease in yield is the same in both cases and is not due to thinning out.

In the second case, one field 12' × 12' was thinned out to a distance of 24' × 24'. The trees which had to be taken out were pollarded and the stems tapped for one month. During this time the permanent trees were rested. After one month all the pollarded trees were uprooted and tapping was resumed on the permanent trees. The average yield during the two months before thinning out was 2.95 and that during the two months following thinning out 2.71 lb. per tapping day. The same figures for the control-field were 2.89 and 2.61 lb. In this case also no decrease in yield, due to thinning out, took place, notwithstanding the fact that 3/4 of the trees had been removed.

II. — In field experimentation with rubber great care must be taken in interpreting results because of the variations that occur in the yield of equal sized plots of rubber even when similarly treated.

Previous papers are quoted (1), in which it is shown that normal va-

(1) COOMBS & GRANTHAM, Field Experiments and the Interpretation of their Results, *Agricultural Bulletin of the Federated Malay States*, April, 1916; WOOD & STRATTON, The Interpretation of Experimental Results, *Journal of Agricultural Science*, III, 4, 1909; BETCH, The Art of Rubber Experiment, *Tropical Agriculturist*, February, 1915. (Ed.)

riations in yields of experimental plots can be allowed for by the use of a single numerical quantity called the "probable error". The smaller the probable error the greater the degree of precision with which results can be interpreted. Increasing the size of experimental plots beyond a certain limit does not decrease the probable error. Further reduction can only be obtained by duplication of plots. To establish a probable error, records of yields from a large number of similarly treated plots over a period of at least one year are required. A probable error may also be established from records of a large number of groups of plots, provided that the plots comprising each group have been similarly treated. The minimum size of plot is ascertained by calculating a series of probable errors for plots of various sizes. The peculiarities of the rubber crop may introduce certain inaccuracies if a probable error is to be applied generally. It can only be settled by experimentation whether such inaccuracies are of sufficient magnitude to render inadmissible the application of a standard probable error for rubber.

In the absence of a standard probable error, the probable error for a particular experiment can be worked out where duplications exist. WOOD and STRATTON have found that the probable error for annual agricultural crops may be taken as 5 %. It may be inferred, from the experiments discussed in the paper, that a probable error for rubber will not be greater than 7.5 % in carefully selected plots each containing at least 100 trees, but more information is required before generalisations can be made. The same authors found also  $\frac{1}{80}$  acre to be the minimum size of plot for annual agricultural crops. No definite evidence is available regarding the minimum size of plot for rubber, but it will certainly be much larger. It may even prove to be several acres.

Actual records are given showing the variations which may naturally occur among even the most carefully chosen experimental plots and the danger which may arise in attempting to interpret the results of an experiment, although preliminary records are available, unless a probable error is applied.

An example is given of the application of the probable error method to a series of 26 tapping experiments which were carried out in triplicate. They were not planned with the idea of applying the probable error method, and present some difficulties; but a good illustration is afforded of how the method can be applied to previous work where duplications exist.

1117 - **Investigations into Different Methods of Tapping and their Influence on the Yield of the Rubber Plants, in Sumatra.** — RUTGERS, A. A. L., in *Mededeelingen van het Algemeen Proefstation der A. V. R. O. S., Rubberserie* No 10, pp. 19-33 + 5 Tables + 2 Figs. Batavia, 1918.

The experiments described were carried out in the Dutch Indies to determine the most economical method of tapping. Two factors have to be taken into consideration — the destruction of the bark and the healing. It has not yet been found possible to counterbalance these two factors. The healing is always unsatisfactory. During several years the author measured the cortical thicknesses in different plantations and found the

thickness of the bealed bark to be always from 1 to 2 mm. less than that of the original bark, that of a bark scarred twice 1 to 2 mm. less than that of bark scarred once, and so on. For this reason attempts are being made to make smaller and fewer incisions whilst still keeping the yield constant.

RESULTS. — 1) An eight and a nine year old plantation which had been subjected to two incisions on a third section, were subjected to one incision on a third. The productions on one of the plantations remained normal, but on the other it first dropped 25 % and, six months later, rose to normal again. This 25 % decrease agrees with that found by other workers (SPRING). It may, therefore, be concluded that the one incision system is superior to the two incisions system since a 50 % decrease in the bark consumed only causes a 25 % decrease in the rubber obtained.

2) The second experiment compared the system of two oblique incisions on a quarter section at the left of a *straight* central channel with that of two oblique incisions on a quarter section communicating in such a way as to give the central channel a *broken* appearance. The results showed the second method to give a yield exceeding the first by 12 %.

3) A comparison of the results obtained with the different systems of tapping showed the yields obtained from 1 cut on a quarter section, 1 cut on a third section and 2 cuts on a quarter section, to be in the following ratios — 100 : 105 : 121.

4) The last experiment was made to compare the effects of daily tapping with those of tapping every other day (with the same system of incision). Tapping every other day gave a yield 30 % below that obtained with daily tapping, but gave an "economy in bark" of 38 %.

These results are certain to increase the tendency to reduce the cuts, and the author believes that, within two years, in the eastern coastal districts of Sumatra nearly all the plantations will have adopted the system of cuts on a third or on a quarter section.

This plant is a small leguminous tree, native of Tropical America, at present growing wild all over the Nilgiris and other hills of South India and acclimatised in many parts of the low country of Ceylon. In Coorg it has been used successfully as a shade tree for young coffee.

It is common in Java, up to 4 000 feet and is used as shade for coffee and for fuel; it is abundant throughout the whole of the low country of Mau-

STIMULANT,  
AROMATIC,  
NARCOTIC  
AND  
MEDICINAL  
PLANTS

VARIOUS CRO

ritius, Reunion, and many parts of Madagascar, being used for fuel and fodder. In the Philippines also it appears to have spread within recent years and is reported as being used there for planting in wild grass lands and as light shade for forest plantations.

*Leucaena glauca* has been used for some years on the Experiment Station, Peradeniya, as a green manure for rubber, and has been regularly cut 4 to 5 times a year with the object of adding humus to the soil. The average quantity of green material per acre per year has been found to be : first year after planting 29 000 lb., second year 77 000 lb. (5 cuttings), and third year 91 900 lb. (6 cuttings). Under these conditions it is kept at an average height of 2 ft.

In Java it is likewise used as a green manure plant. It is commonly employed in young coffee and rubber plantations up to 3 500 feet, and has been experimented with in tea. It is lopped every 3 to 5 months and gives a fair quantity of green mulch per acre. As a green manure in young rubber it was found to be sometimes rather difficult to establish, but where a good cover has been obtained it has stood frequent cutting well, and does not appear to suffer from spells of dry weather. It is used in Java as a light shade for *Robusta* coffee and is being similarly employed at the Peradeniya Experiment Station. It seems to be well suited for this crop. These shade trees are allowed to grow to about 10 feet in height, and they are lopped twice a year, the loppings being mulched around the coffee trees.

In Mauritius, where the plant grows wild over extensive areas of land it is coppiced regularly every year or every alternate year for fuel.

Cattle are very fond of the leaves of *Leucaena glauca*, and in some places herds of goats are housed and fed solely upon leaves of this plant with the object of producing manure. The leaves are rich in nitrogen and potash salts, as the following analysis shows:—ash, 9.26; nitrogen, 2.52; potash, 2.38; phosphoric acid, 0.45 per cent. The seeds are also a valuable food, rich in nitrogen, and may be fed to cattle, sheep, or goats. It should, however, not be fed to horses, as it causes an irritation of the skin, with subsequent loss of hair from the mane and tail, and sometimes coat. Analysis of the seed gave the following average results:—

	Ceylon By agricultural Chemist.	Mauritius By P. BONAME
	Per cent.	Per cent.
Water . . . . .	4.50	9.59
Ash . . . . .	4.55	3.69
Woody fibre . . . . .	14.50	14.00
Fats . . . . .	6.40	4.84
Non-nitrogenous matter . . . . .	40.11	38.24
Nitrogenous matter . . . . .	29.94	29.64
Nitrogen . . . . .	4.79	4.74

The outer coat of the seed is very tough, and forms 50 per cent of its weight. Laboratory tests were made by BONAME in Mauritius in 1897,

when he separated the seed from the seed coat and then analysed them. The results were as follows:—

	Meal from inner part of seed.	Husk.
	Per cent.	Per cent.
Water . . . . .	11.44	12.58
Ash . . . . .	4.78	3.42
Woody fibre . . . . .	7.80	13.90
Non-nitrogenous matter . . . . .	37.09	55.03
Nitrogenous matter . . . . .	31.87	11.87
	100.00	100.00

On account of this hard seed coat, it is usual in practice either to boil the seed until the seed coats burst or to crush the seed dry in an ordinary seed crusher. The latter practice is generally recognised in Mauritius as being the more satisfactory, and is in agreement with the general practice of feeding cattle with dry food rather than with mashes or slops.

In the Philippines it is recorded that *Leucaena glauca* has been successfully used by forest officers against illuk (*Imperata arundinacea*) for it is quick growing and eventually shades the illuk sufficiently to kill it out effectively. It is also used to provide shelter for seedlings in forest plantations. The young forest trees are afforded a light shade by *Leucaena glauca*, and when they have attained a fair size it is cut out and used as fuel. Actual figures are available from the Philippines as to the quantities of fuel yielded by this tree. Experimental plots have yielded average returns of 10 cords (nearly 50 cubic yards) of fuel per acre per year. The wood has a high calorific value, and it is considered to be a high class fuel wood. It has a straight grain, and splits easily (1).

In Java it is reported that plantations of this plant are being made for fuel purposes.

*Leucaena glauca* is also known as a soil renovator. It is the general experience in all countries that soil under this plant subsequently taken into cultivation is of good fertility, and there are instances of poor land being improved by being allowed to remain for some years under it.

#### 1124 — Chemical Composition of the Loganberry (*Rubus Idaeus Loganii*).

— DAUGHTERS, M. R. (Assistant Professor of Organic Chemistry), in *Oregon Agricultural College Experiment Station Bulletin*, No. 151, 10 pp. + 5 Tables + Bibliography of 36 Publications. Corvallis, Oregon, 1918.

HORTICULTURE

After describing shortly the growing economical importance of the loganberry (2) in the United States, the author gives the results of several analyses of the fruit, juice and pulp. The percentages obtained for the fresh fruit were: — Total dry matter 20.74; moisture 79.26; anhydrous citric acid 1.52; invert sugar 7.15; protein (N × 6.25) 4.55; fat 6.13; crude fibre 1.38; ash 0.57.

(1) From the roasted and crushed seeds is made a good coffee substitute (*Revue agricole de l'île de la Réunion*, series X, Year V, No. 12, pp. 344-346. Saint-Denis, December, 1917). (Ed.)

(2) See R., Nov. 1910, p. 79. (Ed.)

The principle acid of the fruit is, therefore, citric acid; there are traces of tartaric acid but malic acid is absent. The pulp which remains after the juice has been extracted may be put to various uses. It may be made into jam or gives an excellent jelly (it is very rich in pectin).

Its use as a food for animals has also been considered, but in this case it would be necessary to neutralise its marked acidity by a suitable addition of sodium carbonate. This pulp may also be used as a fertiliser for, not only does it enrich the soil in organic matter, but also supplies it with a relatively large quantity of mineral matter (phosphorus 1.01 %; sulphur 0.47 %, *ABERN*). Finally when dried, crushed and extracted with petroleum ether, the pulp gives a drying oil the physical and chemical properties of which closely resemble those of linseed oil.

**1125 — A Contribution to the Chemical Composition of Pineapple and the Materials Necessary to its Cultivation.** — GONÇALVES DE SOUSA, J. V., in *Revista Agronomica*, Year XIII, Ser. 2, Nos. 1-4, pp. 26-31 + 9 Tables. Lisbon, 1918.

This paper gives the results of analyses of — a) several samples of pineapple fruits and plants; b) two samples of mould in which the fruit had been grown; c) different materials used for forming the cultural layer ("mata verde, leiva virgem", "mato fermentado, leiva fermentada") which contains *Calluna vulgaris* Salisb., *Erica azorica* Hochst., *Myrsine africana* L., etc.

**ANALYSIS OF THE WHOLE FRUIT:** — Moisture 86.78 %; fat 0.11 %; protein 0.8 %; fibre 0.62 %; ash 0.44 %; ternary extract 11.22 %. A detailed analysis of the ash showed the potassium content to be 0.196 %, a content superior to that of the other minerals.

**ANALYSIS OF THE MATERIALS USED FOR CULTIVATION** (layer, mould, etc.) These results confirm those obtained by the analysis of the fruit and the plant, *i. e.*, that this plant requires above all large quantities of potassium and nitrogen in the form of nitrogenous organic matter.

Assigning to each fruit an average weight of 2 kg. (4.4 lb.) and a weight of 2 kg. to each plant as well, the amount of food extracted from the soil by each thousand plants was; nitrogen 8.1 kg.; phosphoric acid 0.84 kg., potassium 17.50 kg., lime 2.68 kg.

## LIVE STOCK AND BREEDING.

### HYGIENE

**1126 — Immunity Studies on Anthrax Serum (1). Transformation of Pseudoglobulin into Globulin.** — I. EICHORN, A., BERG, W. N. and KESLER, R. A. (Pathological Division, Bureau of Animal Industry, U. S. Dept. of Agr.), in *The Journal of Agricultural Research*, Vol. VIII, No. 2, pp. 37-56 + 6 Tables + 1 Fig. + Bibliography of 11 Publications. Washington, D. C., January 8, 1917. — II. BERG, W. N., *Ibid.*, No. 12, pp. 449-456, March 19, 1917.

I. — The immunity conferred by anthrax serum is of short duration, lasting only a few weeks. To produce a more lasting immunity SOBERN-

(5) See also R. May 1918, No. 543. (Ed.)

HEIM recommended a simultaneous treatment with serum and vaccine. EICHHORN obtained good results from the use of serum and spore vaccine and found the method to possess advantages over the PASTEUR method. Numerous experiments undertaken demonstrated the value of anthrax serum as a curative agent and as a prophylactic when employed simultaneously with anthrax spore vaccine.

Recalling the work on the separation of diphtheria antitoxin by fractioning the serum through the use of ammonium sulphate, the writers applied this method to anthrax serum and succeeded in producing the antibodies in a concentrated form. Chemical analyses of the serum and globulin preparations were made, and the changes in serum proteins during the course of hyperimmunisation of animals against anthrax were studied with the following results:—

Anthrax serum was fractioned by the methods used in the preparation of diphtheria antitoxin. The anthrax antibodies were associated with the pseudoglobulin fraction.

The globulin preparations contained the antibodies in a concentrated form. This was shown in numerous tests on laboratory animals. The preparations were also potent in tests on larger animals, that is, cattle, horses, etc. When administered to human beings infected with anthrax, the globulin preparations were found to have great therapeutic value. However, no data have yet been obtained which permit accurate measurement of the potency of either the serum or the globulin obtained therefrom.

The methods of analysis of serum and similar preparations of globulin have been improved by the use of the centrifuge instead of filtration as a means of separating globulin precipitates from their filtrates. The precipitates are obtained in compact form with a minimal amount of absorbed supernatant fluid. There is no need for reprecipitation.

The changes in the amounts of the serum proteins in a mule undergoing immunisation to anthrax were similar to those usually noted in the serum of animals being immunised to diphtheria, tetanus and rinderpest, that is, there was a pronounced rise in the content of total coagulable protein and total globulin.

Favourable results follow the use of anthrax serum or globulin preparations in the treatment of anthrax in man or animals. The globulin preparation is probably superior to the serum in the treatment of the disease in man, since the dose is smaller, and may be safely given intravenously, and the danger of anaphylaxis is minimised.

The work on the standardisation of anthrax serum by complement fixation, while still in an experimental stage and incomplete, points to the possibility of a more accurate means of standardisation through its employment.

II — In several publications BANZHAF states that when diphtheria serum is heated as it is in the preparation of antitoxin, part of the pseudoglobulin is transformed into globulin. This transformation has both a practical and a theoretical interest. It facilitates the concentration of the antitoxin present in the serum by removing protein without removing any

of the antitoxin, so that the final product contains all the antitoxin associated with much less protein. This is desirable because certain of the serum proteins have very little therapeutic value. On the theoretical side, the fact that pseudoglobulin can be transformed into euglobulin without affecting the total number of antitoxic units is almost conclusive proof that the antitoxin is a substance separate from pseudoglobulin. That this transformation may take place in some serums, but not in all, is indicated by the experiments which the author describes in the paper under review. The writer has applied the heat treatment to the anthrax serum, with the following results:—

The transformation of pseudoglobulin into euglobulin was observed in four serums that had been heated for 30 minutes at 60° C. in the presence of 30 per cent saturation ammonium sulphate. In some instances the amounts transformed were considerable, although in one of the serums the amount was so small as to indicate that the transformation does not take place in all serums.

The methods of analysis were improved by the use of the centrifuge as a means of separating globulin precipitates from their filtrates. The precipitations in the analyses were made at the same dilutions as in the precipitations of globulin for therapeutic use.

**1127—On the Possibility of the *Post Mortem* Generalisation of the Virus of Rabies.—**

REMLINGER, P., in *Comptes Rendus de la Société de Biologie*, Vol. LXXXI, No. 11, pp. 564-566. Paris, June, 1918.

Objection has often been made to those authors who have recorded the presence of the virus of rabies in various organs that their *post mortem* researches should be accepted with caution, since the virus might become generalised after death, either by a sort of multiplication or by a kind of diffusion somewhat similar to that of a dissolving chemical substance. Thus, after finding that the virus diffuses *in vitro* (in physiological salt solution, in Locke's solution, etc.), the author attempted to ascertain whether an analogous phenomenon could take place *in vivo*. He thus attempted to find an answer to the following questions:—

1) *Can the virus of rabies be found, owing to the on-set of putrefaction, in an organ (testicles, seminal vesicles, ovaries) (1) where it can be found neither during life, nor during the first hours after death.*

Experiment gives a negative answer to that question.

2) *Given an organ (suprarenal capsules, spleen) where the presence of the virus is inconstant, does the frequency with which it is found vary according to whether the organ was removed before or after the death of the animal?*

The reply provided by the researches is again negative, or at least it may be said that, according to the two cases, there is very little difference as regards the frequency with which the virus is found.

The author concludes that the *post mortem* generalisation of the virus of rabies is very rare and inconstant; that, in consequence, researches undertaken without taking such an eventual generalisation into account

(1) See R., August, 1918, No. 878. (Ed.)

would not be burdened with an appreciable source of error. The diffusion of the virus *in vivo* is less frequent than that taking place *in vitro*. The author suggests, as the simplest explanation of this fact, that a liquid lends itself better than a solid to "diffusion", which taken as a whole is fairly close to 'dissolution'.

**1128—Efficacy of Some Anthelmintics.** — HALL, M. C. and FOSTER, W. D. (Zoological Division, Bureau of Animal Industry, U. S. Dept. of Agriculture), in the *Journal of Agricultural Research*, Vol. XII, No. 7, pp. 397-447 + Bibliography of 30 Publications. Washington, D. C., February 18, 1918.

Although the use of anthelmintic treatment is an old practice, the efficacy of the various substances employed as anthelmintics is not well known. The available information is based largely on clinical observations or on faecal examinations for worms passed and for eggs persisting in the faeces, which method is somewhat inexact. A more satisfactory one is to treat the animals, collect all the faeces passed for a number of days, and recover from them all worms present, and then to kill the animals and collect all worms remaining. This was the method employed by the authors. Their plan was to test as many drugs as possible having a known or alleged anthelmintic value, abandoning those which gave no results, and making further experiments with the more promising ones. The results are summarised in 5 tables, and, making due allowance for the paucity of data in regard to certain drugs, the writers consider that the following may be reasonably advanced as the result of their investigations.

Simple purgatives, calomel and castor oil, may have some slight value as anthelmintics, but it is hardly sufficient to justify their use for this purpose. Ascarids (*Belascaris marginata*) in dogs are sometimes removed by castor oil given as a preliminary purge, and this fact may prove of benefit in veterinary practice as a diagnostic measure when the more accurate method of microscopic faecal examination cannot be carried out. However, castor oil failed to remove ascarids more frequently than it succeeded, and in no case were all the ascarids removed from any one animal. As many of the experiments on dogs were preceded by a dose of castor oil, the writers have fairly extensive data on this subject.

The most reliable vermifuge for ascarids, whether in dogs or swine (*Ascaris suum*), is oil of chenopodium. This drug, which was tested on 34 dogs in 6 experiments, showed an efficacy for the entire series of 97 per cent. It rarely fails to remove all the ascarids present in a dog if given at the rate of 0.2 mil (milliliter) per kilo, preceded by a dose of castor oil and the animal starved for 24 hours before treatment.

The chenopodium treatment is also very efficacious for ascarids in swine, and when properly administered may be expected to remove most, if not all, of the worms present. It would seem, however, that neither chenopodium nor any other drug tested will give satisfactory results if mixed with the daily ration and the animals allowed to dose themselves; it is best given to each pig individually in suitable dosage, preceded by a fast.

Oil of chenopodium appeared to be effective for stomach worms in sheep

(*Bunostomum trigonocephalum*) although the data on this subject are not sufficient to warrant its recommendation. It is also of some efficacy for hookworms in sheep and in dogs (*Ancylostoma caninum*) though in the latter case chloroform was found more reliable.

Other remedies which seem to have more or less merit as anthelmintics against ascarids are the latex of *Ficus laurifolia*, santonin in repeated doses, and thymol. Although thymol in repeated doses is fairly efficacious against hookworms, it was inferior to chloroform for this purpose, causing more distress. An excellent preparation for mixed infestation in dogs consists of equal parts of oil of chenopodium and chloroform, given at the rate of 0.2 mil per kilo, combined with 30 mils of castor oil. This preparation may be expected to remove all the ascarids present, a large proportion of hookworms, and possibly a certain percentage of whipworms. This latter parasite seems to be very difficult to eliminate, and nothing tried by the writers proved very efficacious, almost any anthelmintic occasionally proving successful. This experience may perhaps be explained by an intermittent peristalsis of the caecum, which occasionally allows the anthelmintic to enter, but which usually excludes it. Although chloroform was fairly successful in removing stomach worms from sheep, both animals upon which it was tried subsequently died from its effects, and it would seem to be too dangerous for use on sheep.

In the case of stomach worms in sheep, copper sulphate (1 % solution ; 100 mils to sheep a year old, 50 mils to lambs under a year old) was found to be the most satisfactory remedy, the experiments confirming the findings of HUTCHINSON. Petroleum benzine also proved satisfactory and was more efficacious for hookworms than copper sulphate. However, it is much more expensive than copper-sulphate solution, must be given three times, and in a vehicle like milk, which adds greatly to the expense. The fact that petroleum benzine (refined gasoline) proved efficacious, while commercial gasoline was considerably less so, is perhaps related to the differences in specific gravity and consequent volatility of the refined product compared with the commercial product.

Among anthelmintics intended for use against tapeworms, male-fern (*Dryopteris filix-mas*) proved efficacious when tested on dogs. In the case of cats it removed all tapeworms from 75 per cent of the animals tested, though it proved fatal to 2 out of 6 animals which were somewhat enfeebled from disease. Apparently it is more toxic to cats than dogs and should be prescribed with caution and only given to healthy subjects. So far as can be judged from a single experiment with dogs, there seems to be no danger in combining male-fern with castor oil, as is done in the so-called Hermann's mixture. In fact, the writers are inclined to agree with SEINFERT (1908) that the administration of castor oil after male-fern will avoid the toxic effect of the latter by causing its rapid and thorough elimination, and that for this purpose no other purgative is quite so effective. This subject, however, should receive more study before conclusions are drawn. Pelletierine tannate was a failure in the one experiment in which it was tested on cats, but was efficacious on dogs. No remedy was efficacious

against tapeworms in poultry. Of the four drugs tested, chenopodium gave the best results for this purpose, but its efficacy for tapeworms is very slight.

Turpentine proved the most efficacious of the remedies tested on poultry for the removal of *Ascaridia perspicillum*, while chenopodium was nearly as good. When tested on dogs and pigs, turpentine was not very efficacious; and, as it caused grave symptoms of nephritis in pigs and caused the death of some of the experiment dogs, its use upon these animals is inadvisable.

The treatment with chopped tobacco stems recommended by HERMS and BEACH for ascarids in poultry proved fairly efficacious for *Heterakis papillosa* and would presumably be at least as efficacious for *Ascaridia perspicillum*, since this latter worm is more easily reached by anthelmintics than is *H. papillosa*.

There are a large number of drugs showing a greater or less degree of efficacy for the various intestinal parasites of domestic animals. Usually their action is selective — that is, they show a pronounced efficacy for certain species of intestinal worms, while they are decidedly less efficacious or entirely inefficacious against other intestinal parasites. If we consider that the ideal anthelmintic is one which will remove all worms of a given class or species, and do this every time in a single dose, we find that very few drugs approach this ideal.

Among the drugs which have given the best results under experimental conditions for the purposes intended and concerning which the writers have sufficient data to warrant positive conclusions may be mentioned the following:—

- 1) Copper sulphate in drench for stomach worms in sheep.
- 2) Oil of chenopodium for ascarids in pigs and dogs.
- 3) Oleoresin of male-fern for tapeworms in dogs.
- 4) Turpentine for *Ascaridia perspicillum* in fowls.
- 5) Chopped tobacco stems for *Heterakis papillosa* in fowls.

#### 1129 - The Destruction of Ticks Found on Domestic Animals in New Zealand. —

REAKES, C. J. (Director, Live stock Division), in the *New Zealand Department of Agriculture, Industries and Commerce, the Journal of Agriculture*, Vol. XVI, No. 2, pp. 83-86. Wellington, February 20, 1918.

Ticks have been found to be unusually prevalent upon cattle, dogs, horses, and occasionally sheep, in portions of the northern Auckland district of New Zealand but their presence does not imply the existence of piroplasmosis (tick-fever), which has never been present in the Dominion. Two ticks have been found — *Ixodes ricinus* (dog-tick, or castor-bean tick) and a species of the subfamily known as *Hæmaphysalis*.

Each year these ticks are first noted about August and September and they are most numerous in November and December. During January their numbers diminish, and between February and August little of nothing is seen of them.

As long as tick fever is kept out of the Dominion there will be nothing to fear from the ticks on that score; but, if they become too numerous they

may cause trouble: — *a*) by lowering condition through loss of blood; *b*) by decreasing the milk-yield; *c*) by deteriorating the value of the hides; *d*) by causing death in animals already weakened by other diseases, insufficient food, etc.

The officers of the Livestock Division have experimented with methods for destroying the parasites, and found that, in the case of dairy cows and other cattle which can be handled, spraying with Stockholm tar is an effective method, as the ticks are killed by it in a few hours. As regards run cattle, unaccustomed to handling, dipping is the only effective method available. The tar is sprayed on the infected parts of the skin by means of the "Faultless" spray-pump, which is quite cheap and was originally sold for spraying garden plants, etc.

Other spraying preparations tried were as follows: —

- 1) Kerosene  $\frac{1}{2}$  pint, linseed-oil  $\frac{1}{2}$  pint, sulphur 1 oz.
- 2) Kerosene 10 oz., lard 10 oz., tar 2 oz., sulphur 1 oz.

These two mixtures, however, though they ultimately destroyed the ticks, proved much slower in their action than the Stockholm tar. Very strong solutions of sheep-dips also proved effective, but sometimes irritating to the animals.

**1130 — On a Mite of the Genus *Tyroglyphus*, an Accidental Parasite of the Horse.** — CARFANO, M. (Bacteriological Laboratory for Military Veterinary Medicine, Rome), in *La Clinica Veterinaria*, Year XLI, No. 7, pp. 173-177 + 1 Fig. Milan, April 15, 1918.

In the crusts and hairs removed from quadrupeds suspected to be suffering from mange, besides the mites parasitic on other animals (obligatory, stationary, permanent parasites) belonging to the family *Sarcoptidae*, sub-family *Sarcoptinae* (with the 3 genera *Sarcoptes*, *Psoroptes*, and *Chorioptes*) and to the family *Demodecidae* (genus *Demodex*), other mites may be found as temporary parasites such as those of the family *Gamasidae*, the common parasites of poultry, and other insects (accidental parasites) incompletely determined which normally live on seeds, forage, old wood, sweepings, etc. Amongst these latter, some species of the sub-family *Tyroglyphinae* of the family *Sarcoptidae*, are of interest, either because they may be mistaken for the common mites truly parasitic on the horse, or because, as is the author's opinion, they can, under determined conditions, exercise a certain pathogenic action on the horse.

Some of these species normally live on vegetable and animal organic matter, usually decomposing, and on which they feed. Others are parasites of the larvae of grain-eating insects that infest all kinds of cereals and other food-stuffs. These mites may attack man, causing skin irritation sometimes accompanied by fever ("vanillismus" of workers handling vaniline; "water itch" of the Indian tea planters; grocer's itch; harvest fever; etc.). Veterinary pathology has shown the possibility of finding specimens of *Tyroglyphinae* on the skin of animals, but, as far as the author is aware, there has yet been no record of the possibility of their causing a pathogenic action on the skin itself.

The author has seen dermatosis on the lips, spreading to the cheeks

and nose of the horse, produced by mites of the genus *Tyroglyphus*, which he describes and illustrates. These accidental ectoparasites probably come from fodder. They can be distinguished from the true mange mites by 1) their elongated body; 2) the clear division between the cephalo-thorax and abdomen; 3) the absence of striae on the body; 4) all the 4 legs being uniform and provided with suckers.

1131 - Experiments on the Treatment of "Tristeza" in the Argentine. — QUEVEDO, J. M., in *El Campo*, Year II, No. 219, pp. 267-268 + 2 Figs. Buenos Aires, May, 1918.

The author (Sub-Director of the Bacteriological Institute of the Ministry of Agriculture of the Argentine Republic) calls attention to the fact that "tristeza" occurs in two forms — piroplasmosis or babeosis, caused by *Babesia bigemina*, and anaplasmosis, caused by *Anaplasma bovis* (1).

PIROPLASMOSIS. — Quinine compounds, and especially the bichlorhydrate, on account of its solubility, stimulate the secretions of the sick animal, which helps greatly towards recovery, but they neither decrease the numbers of the parasites nor cause any notable modification in their structure. For grave cases the author advises intravenous injections of 5 to 8 gm. of bichlorhydrate of quinine dissolved in 25 to 40 cc. of water, or 10 to 20 gm. of quinine sulphate dissolved in  $\frac{1}{2}$  a litre of water given by the mouth; the doses can be given after every 24 hours. Fractional doses, when given immediately when the first symptoms of the disease appear, may give good results with the slowly-developing forms. Other febrifuges (e. g., antipyrine) did not give as good results as quinine.

Amongst arsenical compounds, sodium cacodylate, arrhenal and atoxyl have been repeatedly tested by the author, who has found that though they act favourably they have no decisive influence on the course and issue of the disease.

During the acute period, colloidal silver (lichtargan, collargol, protargol) reduce the temperature, but have no decisive influence on the course of the disease.

Aniline dyes, and especially trypan blue, were found to be decidedly efficacious against the parasite. Trypan red has also given good results, while safranin and neutral red were less successful.

Salts with a purgative action, such as magnesium sulphate, are always useful in the treatment of bacteriosis. Stimulants (coffee, etc.) are also useful.

During the course of the disease, fresh forage, roots and decoctions should be given, while the grain and hay should be restricted.

ANAPLASMOSIS. — Trypan blue, trypan red and the other aniline compounds that are efficacious against piroplasmosis are inefficacious against anaplasmosis. Slightly better results have been obtained with a single dose of 3 to 4 gm. of atoxyl injected in the jugular. Very poor or worthless results were obtained with salvarsan (2 gm. injected in the jugular) and colloidal silver. Opening medicine and febrifuges are useful.

(1) According to other authors these are two phases of the same disease. See R., July, 1918, No. 777. (Ed.)

In conclusion, there are no therapeutic agents that suffice to combat anaplasmosis.

**1132 — Two Flukes from the Dog.** — HALL, M. C. and WIGDOR, M. (Research Laboratory, Parke, Davis & Co., Detroit, Mich.), in the *Journal of the American Veterinary Association*, Vol. LIII, New Series Vol. 6, No. 5, pp. 616-626 + 7 Figs. + Bibliography of Publications. Ithaca, N. Y., August, 1918.

Up to the present the only fluke reported from the dog in the United States is *Paragonimus kellicotti*, which occurs in the lungs of dogs, cats and swine. The authors made a post mortem examination of 300 dogs at Detroit, and found intestinal flukes in 7 animals. The flukes belonged to 2 different species, which are new to science, and which the authors name *Alaria americana* and *A. michiganensis*, the specific diagnosis being also given.

#### FEEDS AND FEEDING

**1133 — Albuminoids in the Feeding of Live Stock.** — WIEGNER, G. (Contribution from the Agrikultur-chemischen Institut der Eidgen. Technischen Hochschule, Zurich), in *Landwirtschaftliches Jahrbuch der Schweiz*, Year XXI, No. 1, pp. 42-64. Berne, 1918.

After considering generally the feeding of cattle the author discusses at length the part of albuminoids therein and shows that, in the new discussion on the minimum quantity of albuminoids necessary in the feeding of man and animals (raised by the shortage of albuminoids and their rise in price through the war) account must be taken to a far greater extent than has hitherto been done of the biological value of the albuminoids, of the qualitative composition of the foods and fodders and the variable degree of digestibility. It is necessary to distinguish between the relative minimum and the absolute minimum of albuminoids necessary in feeding because the physiological laws are not yet known with sufficient exactitude and there is as yet no feeding technique sufficiently trustworthy to make it possible to restrict either men or animals to the "absolute minimum" of albuminoids (which is, for example, 30 gm. for a man and from 100 to 125 gm. for cattle weighing 500 kg.).

The author believes that, even in times of scarcity, the absolute minimum of albuminoids must be doubled if waste of other food elements of great value is to be avoided, and especially if derangement of the organism is to be guarded against. He shows the reasons, based on abundant experimental data, which led him to form this opinion and shows the figures given later to be probably correct for the albuminoid requirement of live stock in so far as our theoretical and practical knowledge of feeding will enable us to judge.

It is possible that the absolute minimum of albuminoid requirement for cattle weighing 500 kg. may be reduced to 100 to 125 gm. of digestible albuminoids in the ration, but most workers agree, and rightly so, that 250 gm. is the minimum amount of digestible albuminoids which should be fed. In a diet requiring the greatest possible economy, as in the case of that imposed by the war, this figure may, at the most, be reduced to 200 gm. of digestible albuminoids in the fodder given.

Under better feeding conditions and with albuminoids of high biological value it is possible to recover, in the form of milk albumin, all the albuminoids fed, in addition to that which is indispensable to the main-

tenance of the dairy cow. It is also possible in practice and under the experimental conditions adopted by the author, to cause 350 gm. of digestible albuminoid contained in a ration to be transformed into 350 gm. of albumin contained in 10 litres of milk with a 3.5 % albumin content. KELLNER, however, recommends under the same conditions almost a double quantity, that is to say 550 to 650 gm. of digestible albuminoids for 10 litres of milk.

If, instead of considering the starch value only, account is taken of the qualitative composition of the food according to the rules given in this paper, the quantity of albuminoids required to produce 10 litres of milk may be reduced to 450 gm. FINGERLING believes it possible to reduce this figure to 400 gm., but, as the author justly points out, it is precisely in feeding for milk production that a limited excess of albuminoids most rarely represents a wastage of albuminoids. Growing animals can also transform a quantity of albuminoids exceeding that which is indispensable for maintaining the albumin which accumulates in the tissues of the animal providing, of course, that this is under improved conditions of feeding and development such as specified by the author. As these conditions are very difficult to realise in practice the author recommends that, in this case too, the figure given for the absolute minimum be doubled.

For growing calves the author recommends in time of war demanding the greatest possible economy the following figures drawn up by FINGERLING: —

Age of animals  <i>months</i>	Live weight  <i>kg.</i>	Minimum quantity required for 1000 kg. of live weight	
		Digestible albuminoids in maintenance ration  <i>gm</i>	Digestible albuminoids in fattening or production ration  <i>gm</i>
2-3	70	400	2 200
3-6	140	400	1 800
6-12	240	400	1 300
12-18	320	400	800
18-24	400	400	600

These rations must be considered as "minimum war rations"; their values are 25 % below those given by KELLNER.

The amount of albuminoid necessary for growing pigs has not yet been fixed definitely and new investigations are necessary. The author's calculations, however, show that, for growing pigs, the minimum quantity of digestible albuminoids is from 60 to 80 gm. per head daily, though according to FINGERLING an average quantity of 30 to 40 gm. is sufficient. It is known that pigs under good growing conditions respond well to albuminoids in the ration.

For a complete ration (maintenance ration + production or fattening

ration) LEHMAN recommends 250 to 300 gm. of digestible albuminoids per head daily, whereas FINGERLING reduces these figures to 100 to 200 gm. By numerous practical experiments on the intensive and rapid fattening of pigs (from 20 to 110 kg. in 5 or 6 months) LEHMAN showed that the rather large quantity of albuminoid he advises gives good results and proves profitable though admitting that when necessary it may be decreased to 200 gm. as shown by the author.

The author also shows that a ration deficient in albuminoids may often cause serious derangements, especially in growing pigs. In view of the uncertainty of calculating theoretically the quantity of albuminoids to be given to pigs he recommends the use of empirical rules for feeding which would lead to good practical results and could also be used in war time when the shortage of albuminoids is more keenly felt. Some of these principles and rules for feeding pigs are taken from the works of LEHMAN on this subject.

**1134 - The Treatment of Lupins in Order to Eliminate their Toxic Properties; Researches in Holland.** — BOODT, in the *Tydschrift der Nederlandsche Heideemaatschappij*, Year XXX, No. 3, pp. 68-70. Wageningen, 1918.

Description of a method for removing the poisonous substances contained in lupins:— a vat is half-filled with lupins, then filled up to the brim with water and left to stand for 24 hours. The lupins, which are nearly dry, are placed in another vat full of fresh water, boiled for 3 hours and left to cool for 12 hours. They are again removed to another vat containing fresh water, where they remain for 12 hours; they are then crushed with a wooden mallet. The author admits that the process is not very rapid, and points out that it is necessary to proceed cautiously and safely in order to avoid the slightest trouble in feeding.

When lupins treated in this way were fed to cattle just as they were, their food value was not very great as the greater part of them were found undigested in the faeces. Their digestibility had therefore to be increased, and to obtain this the author mixed them with finely chopped ("hacksel") oat straw. This mixture then formed an excellent food for cattle; about 22 lb per head and per week suffice for working oxen and if they are given no concentrated food stuffs the quantity mentioned may be doubled or tripled. The feeding value of the lupin is obvious when its starch value (74.2 for 100 kg.) is compared with that of the horse-bean (66.6).

**1135 - Vine Fodder: The Value and Utilisation of Vine Leaves.** — SEMICHON, L., in the *Revue de Viticulture*, Year XXV, Vol. XLVIII, No. 1252, pp. 401-406 + 2 Tables. Paris, 1918.

Districts devoted especially to vine-growing are bound to suffer more severely than others during critical periods because most of the necessities of life must be imported. It is, then, especially necessary for the inhabitants to utilise every bit of utilisable matter produced in the district, and above all, in the vineyards. The leaves and shoots of the vine, usually wasted, have a very real food value. The trimming and pruning of the vines during the periods of vegetation and flowering remove a considerable quantity of leaves and young shoots which are left on the soil but which,

if collected, would make excellent fodder for horses and permit of an economy of hay and alfalfa. It would be best to collect the leaves in autumn, after the vintage, as there are then at least 1 lb. (and even 2 or 4 ½ lb.) per plant. Allowing there to be 620 plants per acre, a yield of about 16 cwt. per acre would be obtained, or 5 acres would give enough leaves to feed a horse for one year.

The results of analyses of this material (KELLNER, MALLÈVRE) are given and compared with those obtained for good meadow hay or good alfalfa hay. These results show the starch value (for 100 parts of food) for vine leaves, meadow hay and alfalfa hay to be 42.5, 36.2, 22.4 respectively, i. e., that 90 lb. of vine leaves equal 100 lb. of meadow hay, and 53 lb. equal 100 lb. of alfalfa hay. If this material is not used it is, therefore, because of practical difficulties or other objections, three of which the author examines:

1) *Is stripping off its leaves in autumn injurious to the vine* — Not at all. On estates owning flocks it is customary to let the sheep pass among the vines immediately after the vintage and no weakening of the plants has ever been observed. Moreover, the stripping might be modified to a certain extent. From a point of view of diseases, especially mildew, stripping the leaves is most beneficial as the spores which transmit the disease from one year to another and form in the "mosaic spots" of the autumn foliage, are thereby largely removed.

2) *Does not the collection of the leaves entail practical difficulties?* — Two methods may be adopted: the branches might be cut leaving 5 or 6 buds at the base, the leaves and branches thus being collected together, or only the leaves might be collected. The second method is the more economical as the first is only advantageous if the branches are utilised. If the branches are already lignified they require the use of a mechanical crusher (4 to 5 HP). Their food value is very similar to that of grape stalks, the starch value of which is only 7.7.

3) *Do vine leaves keep well?* — As wine leaves are less moist in autumn than meadow hay or alfalfa, it would be sufficient to pile them up in a shed, as is done with dry fodder. It is, however, wiser to put them in a silo either alone or mixed with residue, piled up well in a tiled pit or in troughs. When the leaves and branches are collected together ensiling is indispensable as the leaves contain more natural moisture than the branches. The profit made, food value and preservation are, thus, all in favour of collecting the leaves only. There is no danger that the action of copper salts which remain on the leaves may injure the health of the animals. Taking into account all the expenses incurred (collecting, ensiling), this fodder would cost 4s. per 220 lb. It is therefore, most economical, especially at a time when hay and alfalfa cost at least 24s. per 220 lb.

1136 — *Tree Leaves in Live Stock Feeding.* — I. I. HOSTE, A., in *La Vie agricole et rurale*, Year VIII, No. 27, pp. 23-24. Paris, July 6, 1918. — II. EZENDAM, F. A., in *Nederlandsch Weekblad voor Zuivelbereiding en Veearts*, Year XXIV, No. 16, p. 2. Doetinchem, 1918.

I. — The author (Director of the Mans slaughter houses, France) shows the value of tree leaves in the feeding of live-stock. The food value of

the leaves varies according to the vegetative period and the plant: as a rule it is higher in June and July than in September, and the leaves from the higher parts of the tree are richer in fibre. The plants containing the most nitrogen are alder, acacia, elm, lime, oak and maple.

The results of several chemical analyses made by M. A. CH. GIRARD (Professor of the Institut national agronomique) are given in detail. The average food value, in food units, of tree leaves at the end of July is 37.7, and that of meadow hay 31.

The leaves may be fed either green or dry. Green and dry leaves may be given to animals in the following quantities respectively:— horses and mules, 11 to 17.6 lb., 8.8 to 11 lb.; oxen, 22 to 33 lb., 13.2 to 22 lb.; sheep, 5.5 to 6.6 lb., 2.2 to 3.3 lb. Various specimen rations are then given:—

*For horses of 1100 lb.* — 1) green leaves 17.6 lb., oats 8.8 lb., straw 4.4 lb.; 2) dry leaves 9.9 lb., oats 11 lb., straw 3.3 lb.

*For oxen*: — 1) maintenance ration: dry leaves 14.3 lb., oat straw *ad lib.*; 2) working ration: dry leaves 22 lb., boiled potatoes 44 lb., rape cake 2.2 lb.

*For cows of 1100 lb.*: — 1) dry leaves 55 lb., straw *ad lib.*; 2) dry leaves 17.6 lb., boiled potatoes 41.8 lb.

*For sheep*: — 1) green leaves 6.6 lb., straw *ad lib.*; 2) dry leaves 3.3 lb., straw *ad lib.*

**TWIGS.** — Twigs with leaves are called "summer twigs", those without leaves, "winter twigs". The true food value in food units is 12.6 for acacia twigs, 13.2 for poplar twigs, 12.9 for beech twigs (negative value because the work of digestion is superior to the number of calories obtained from the food), as against 31 for hay.

Chopped, fermented twigs and non-chopped dry twigs may be fed in the following proportions respectively: — horses and mules 6.6 lb., 8.8 to 13.2 lb.; oxen 16.5 lb., 22 to 26.4 lb.; sheep 1.1 lb., 2.2 to 4.4 lb. The following rations are recommended for oxen and cows:—

1) chopped summer twigs 16.5 lb., chopped straw 6.6 lb., rape cake 4.4 lb.; salt 1.1 lb.; 2) crushed winter twigs 26.4 lb., chopped straw 6.6 lb., potatoes 11 lb., rape cake 1.1 lb., salt 0.22 lb.

**MISTLETOE.** — This may be fed fresh or dry; in the latter case it is chopped. It may be fed in amounts of 4.4 to 6.6 lb. to horses and mules, 4.4 to 13.2 lb. to oxen and 1.1 to 2.2 lb. to sheep and goats. The following rations are recommended:— *for dairy cows*:— mistletoe 13.2 lb., hay 4.4 lb., beet 44 lb., fine straw 4.4 lb., bran 3.3 lb., groundnut cake 3.3 lb.; *for sheep*:— mistletoe 2.2 lb., beet 11 lb., bran 2.2 lb.

II. — According to the author (of the Royal Agricultural Experiment Station of Wageningen, Holland) the food value of dry leaves is about equal to that of medium quality hay. The date and hour at which the leaves are harvested influences their food value. The dry matter content is highest and the nutritive constituents most abundant in July and August. Towards autumn the tannin content increases and digestibility is no longer so good. The leaves are obviously richest in starch in the evening owing to the formation of chlorophyll. Dry leaves must not be exposed to the sun and must be protected from rain. Trees capable of supplying suitable food are

acacia, birch, elm, poplar, lime, chestnut, ash and willow; beech and oak are less suitable.

- 1137 — **Investigations into the Composition of Seaweeds with a View to their Utilisation as Cattle Food, in the Netherlands** (1). — DE BRUYN, B. R. (Director of the Royal Agricultural Station for the Control of Cattle Foods, at Wageningen), in *De Veldbode*, No. 807, pp. 504-505 + 2 Tables. Maastricht, 1918.

In order to utilise all available material in the best possible manner so as to remedy the increasing shortage of cattle food, the Royal Agricultural Station at Wageningen for the Control of Cattle Foods analysed specimens of seaweeds. On a water-free basis, the composition of *Zostera marina* was: — Albuminoids 20.6 %; true albumin 16.9; digestible albumin 4.2; fat 1.6; starch 38.6; crude fibre 14.8; ash 24.4; sodium chloride 12.7 %.

Samples of Fucaceae were also analysed. Their albumin content is not high owing, according to WERENSKIÖLD, to the presence of tannic acid which, with the albumin, forms an insoluble compound on which experiments have shown pepsin to have no action. The experiments of SOLLIED in Norway, and those of the author have not revealed the presence of tannic acid. The food value of the seaweeds must, then, be attributed rather to their starch even though they have not a high carbohydrate content. The low crude fibre content of the *Fucus* is, however, an advantage.

The few known examples of the previous use of seaweeds as cattle food are quoted. In Ireland, Scotland and the Faroë Islands, dried seaweed is used as a winter feed for cattle and horses, in southern Sweden and Zealand as a food for swine. In Germany, since the war, special instructions have been given with respect to the gathering of seaweeds. They are spread out so that the rain can wash out the sodium chloride sufficiently; they are then suitably dried and baled in a press. Washing with soft water is indispensable as many seaweeds (the "brown algae") contain a mucilaginous nitrogenous substance, algine, which with lime and magnesia forms insoluble compounds which would diminish the food value if hard water were used.

In the absence of other roughages, therefore, seaweeds may be fed to cattle when the sodium chloride has been sufficiently removed.

- 1140 — **Cross Between Sheep and He-goat and Between Goat and Ram, in Brazil** (2). — *Chacaras e Quintaes*, Vol. XVII, No. 5, p. 368 and No. 6, p. 466; Vol. XVIII, No. 1, p. 26. São Paulo, May 15, June 15, July 15, 1918.

Senhor OSCAR CANTEIRO reports the existence at Porto Alegre of crosses between sheep and he-goats which are very fine, and have long wool

SHEEP  
AND GOATS

(1) Algae are already being collected in several countries, chiefly for use as fertilisers or as raw material for chemical industry. See *R. Dec.*, 1916, No. 1261 and *R. Jan.* and *Feb.*, 1917, Nos. 91 and 123. As regards their use as cattle food, see *R.*, March 1918, No. 320 and Sept. 1918, No. 1020. (*Ed.*)

(2) See also *R. August*, 1918, No. 889. (*Ed.*)

of the best quality. In view of the long life of these crosses he bred selected sheep to a he-goat of the Toggenburg breed.

According to a correspondent of the periodical *Chacaras e Quintas* of Correntes (Matto Grosso, Brazil) crosses between rams and goats occur commonly in that State. He himself has a small troupe of goats bred exclusively to a ram. The progeny of the cross, locally called "cabrão", have the appearance of kids of a wool breed, but the wool is not curly.

Dr. FERNAND RUFFIER, in his work "*Manual Prático de Criação do Gado no Brazil*", describes the Mexican "cuino", a cross between a goat and a ram which only lived a few days.

## PIGS

1141 — **The Utilisation of the Stomach Contents of Slaughtered Cattle for Feeding Pigs.** — *Feuille d'Informations du Ministère de l'Agriculture*, Year XXIII, No. 24, p. 10, Paris, June 11, 1918.

Amongst farm animals, the pig is that which best utilises all household or commercial waste of animal or vegetable origin and it does not reject food substitutes which would not easily be accepted by ruminants. Slaughter-house refuse can quite well form part of the pig's daily ration even if it cannot form the whole of it. As an example of such refuse, the blood and stomach contents of slaughtered cattle may be mentioned.

At the moment of slaughtering the stomach of a ruminant contains various sorts of masticated food mixed with mucus and gastric juice. These foods are in a more or less advanced state of digestion, having been acted on by bacteria and the gastric juice for a varying period of time.

In France, by a circular of the Ministry of Food Supplies relating to the previous notice issued by the Director of the National School of Veterinary Medicine at Alfort, the possibility has been shown of feeding pigs on the stomach contents of slaughtered cattle (Circular of July 18, 1917, published in the *Journal officiel de la République française*, July 19, 1917, p. 5587).

On the other hand the German Minister of Agriculture has directed the prefects to order the directors of slaughter-houses in their administrative districts to distribute such refuse free of charge, if that is possible, to those interested that apply for it. Instructions were also added to obtain a better food ration for pigs by using 220 lb. of stomach contents plus 4.4 galls. of blood, 44 lb. of turf treated with molasses, 3.3 lb. of salt and a little chalk. It was admitted that 100 lb. of this mixture had the same food value for the pig as 400 lb. of potatoes.

As it is difficult to obtain turf treated with molasses, it may be replaced by an equal quantity of raw or cooked mangold sliced into fingers.

## FISH CULTURE

1142 — **Researches on the Specific Distinction Between the River Trout, Lake Trout and Sea Trout and the Acclimatisation of Fresh Water Trout to Salt Water** (1). — MURISER, W., in the *Archives des Sciences Physiques et Naturelles*, Year CXXIII, Period 4, Vol. 46, pp. 97-99. Geneva, 1918.

On account of the existence of numerous intermediate forms the list of which is continually increasing, the specific distinction between the lake

(1) See also R., January 1918, No. 70. (Ed.)

trout (*Trutta lacustris* L.) and the brook trout (*T. fario* L.) tends more and more to disappear. For some years the author has made numerous observations on the Lake Lemman trout (*Salmo lemanus* Cuv.), always using individuals hatched from eggs of the same spawning and artificially fertilised, in order to study the mechanism of the gradual formation of the colours. In this way he found that the factors of lighting and oxygenation of the hatcheries, when they act from hatching onwards, can, after 10 months, cause the appearance of 3 sorts of colouring in the trout:— 1) facies of the deep-water, lake trout; 2) facies of the surface lake trout or silver trout; 3) facies of the typical brook trout.

The specific difference between the sea trout (*Trutta trutta* L.) and the brook trout (*T. fario*) is also questionable; CLIGNY'S researches have shown that hereditarily sedentary brook trout can pass to the sea and become sea trout thanks to their preadaptive deep-sea character. The author attempted to ascertain whether this preadaptive character belongs to all the fresh-water trout by carrying out the following experiment:— Lake Lemman trout (this species has inhabited that lake for 10 centuries, according to historical data) were placed in artificial sea water, whose salinity was increased in equal quantity every 24 hours; the subjects were descended from the same father and mother. It was found that a subject can pass suddenly, even every 24 hours, from fresh to salt water of 21 per 1000 strength and even at 35 per 1000 (a salinity equal to that of the Atlantic, according to THOUET) with complete indifference, only showing a slight disturbance due to the different density of the two solutions. The subjects lead an absolutely normal life, and, more voracious in the salt water, develop more rapidly than the control specimens kept in fresh water.

In this experiment, 5 months were sufficient for a lake trout, the descendant of innumerable generations inhabiting fresh water, to become acclimatised to a salinity equal to that of the Atlantic.

1143 - The Death of Carp Suffering from *Cyclochaetosis*, Observed in Italy. — SUPINO F., in the *Reale Istituto Lombardo di Scienze e Lettere, Rendiconti*, Series II Vol. LI, Pt. 6-7, pp. 314-316. Milan, 1918.

The author has noted in the Aquarium at Milan a heavy mortality of mirror carp due to *Cyclochaeta domerguei*. This ciliate had attacked the branchiae, which were very congested, covered with a white film and numerous irregular spots. Up to recently this parasite had only been found in aquariums; Sig. MAZZARELLI (On some diseases of Fish and Crayfish observed in Lombardy, *Atti del III Congresso nazionale della Pesca tenu-tosi in Milano nel 1906*, Milan, 1908) has found it on the gills of shad from Lake Lugano, thus showing it occurs in open water.

*Cyclochaeta* attacks various species of fish; it usually attacks trout and carp, as well as eels, etc.; the author has seen it on some specimens of sun perch and trout-perch in the Milan Aquarium. In scientific literature it is considered as a skin parasite that may invade the gills. In the cases observed by the author on carp, the parasite, very abundant on the gills, to which it was attached by the sucker-shaped lower part of the body, was, on the contrary, completely absent from the skin which was perfectly normal.

As means of control good results have been obtained by repeatedly immersing the carp for 15 to 20 minutes at intervals of 3 to 4 days in a 2 % solution of sodium chloride. The tank containing the fish disinfected with lime and left dry for some time. When the disease is less advanced, it is sufficient to use a very dilute solution (1 per 500 000 or less) of potassium permanganate, which can be run, using the necessary precautions, directly into the tank ; in this way the treatment will be much cheaper.

## AGRICULTURAL MACHINERY AND IMPLEMENTS.

### AGRICULTURAL MACHINERY AND IMPLEMENTS

1144 - **Motoreculture by Electricity.** — GOUY, P., in the *Revue de Viticulture*, Year XXV, Vol. XLVIII, No. 1232, pp. 87-89. Paris, February 7, 1918.

After discussing the part that motoreculture by electricity should play and its advantages, the author states that if electrical motoreculture is to be more generally possible, the large electric works — at present rather scattered and supplying energy chiefly for the urban and industrial centres — should not be depended upon too much, but rather that recourse should be had to other sources of electricity which already exist and could be utilised with advantage.

In the mountains as well as in the hill and plain country there are thousands of little waterworks, mills, etc., which often have more power available in the season than they can utilise. It would be very easy to install turbines or water wheels to drive dynamos, which at small cost would supply a few horse-power to the surrounding estates. This power, divided among the farms, would not only light the houses and stables, but would also run fixed motors for farm work and movable motors for cultivating the soil. In France it is estimated that such small sources give a total of about 1 million H.P., a figure that could be much increased. In fact, many small falls in the country districts of France are not utilised at all. With the help of local initiative, either private, communal or from syndicated groups who would divide the energy among themselves or supply their neighbours, hydro-electric installations could easily be established. Such simple and efficacious combinations would have the advantage of generalising the use of electricity for cultivation and of hastening the utilisation of the water-power as well as the most necessary agricultural progresses.

The author quotes the Senator CHAUVÉAU as to the prices of the H.P.-hour for ploughing : — 1) with a steam windlass locomotive burning 7.7 lb. of coal at 24s. 9d. per ton the cost is 1.92d; 2) with a paraffin engine, 1.44d; 3) with a high-tension electric current at 0.96d. the kilowatt the cost is 0.08d. He also quotes the French Minister of Agriculture, M. F. DAVID, to the effect that the water-power kilowatt used for cultivation costs from 0.38 to 1.42d., while that obtained from coal costs 1.42 to 3.14d. when coal cost 32s. a ton.

**1145 - Public Mechanical Cultivation Trials Organised by the French Ministry of Agriculture and Food Supplies at Noisy-le-Grand, France, in Spring, 1918. —**

I. RINGELMANN, M., in the *Bulletin de la Société d'Encouragement pour l'Industrie Nationale*, Year CXVII, Vol. CXXIX, No. 3, pp. 541-554 + 16 Figs. Paris, May-June, 1918. —

II. *Le Genie Rural*, Year X, Nos. 82 and 83, pp. 8-13 and pp. 10-12 + 12 Figs. Paris, 1918.

I. — The French Ministry of Agriculture and Food Supplies has organised mechanical cultivation trials which took place from April 4 to 10, 1918. There were 55 machines entered by 38 exhibitors but only 36 machines entered by 23 makers or agents actually took part. Amongst these 14 machines entered by 9 exhibitors were of French make, while 22 machines entered by 14 makers or agents were of American make. The 1918 trials were organised with the sole object of putting farmers in touch with the makers or their representatives.

The machines that took part may be classified as follows : —

Cable tractors : — 1) Windlass, 1 French machine ; 2) windlass-tractor, 2 French machines ; 3) Haulage-tractor, 1 French machine.

Tractors : — 8 French and 20 American machines.

Motor-plough : — 1 French machine.

Front-wheel tractor : — 2 American machines.

Rotary cultivator : — 1 French machine.

As most of the machines have already been described or noted, the author only gives details for those machines that have not been previously examined.

Among the French-made machines the author quotes : —

1) The machines of M. MARCEL LANDRIN, of Paris : — 1 apparatus for changing a motor-car frame into a tractor and 1 apparatus changing a motor lorry into a windlass-tractor (1).

2) The windlass-tractors (2) of the "Société française des tracteurs-treuels V. DOISY", of Issy-les-Moulineaux, with a 25-30 H.P. engine.

3) The haulage-tractor of MM. FOLTZ, ELMLINGER and CAILLARD, of Juvisy-sur-Orge (Seine-et-Oise), driven by a 30-40 H.P. engine ; if required this machine can work as a direct tractor.

4) The tractor of M. B. CHAPRON (Fig. 1), of Puteaux (Seine), driven by a 4 cylinder engine, of 60 mm. bore and 120 mm. stroke, giving 10 H. P. at 1200 revolutions per minute ; cooling by thermosiphon, radiator and fan ; 3 speeds of 5806, 9843 and 16404 ft. per hour with direct drive on the low speed used for ploughing.

The driving shaft connects to each wheel through a claw clutch with 4 notches ; there is no differential ; to turn, the wheel on the side of the turning centre is thrown out of gear and braked. In this way it turns with a radius of 5 ft. 5 in., while the wheel-base is 6 ft. The driving wheels are 43 in. in diameter while the tyre is 4 in. wide. A hauling windlass could easily be mounted on the driving wheels, when the machine could be used for digging, pulling-stumps, moving loads on a steep slope, etc.

The wheels, whose position on the axle can be varied as, for example,

(1) See R., February, 1918, No. 208 ; R., August, 1918, No. 892. — (2) See R., August, 1917, No. 753. (Ed.)

in the case of hoeing, are 24 in. in diameter. The front-carriage does not press heavily on the soil but when the traction passes a certain limit, it must be loaded with an extra 360-370 lb.

Fig. 1. — CHAPRON tractor.

The engine is mounted on springs so that it can be used for road transport.

Fig. 2 — DIMPRIE tractor.

The total length of the tractor is 8 ft. 10 in. and its greatest width is from 36 to 38 in. ; it weighs 2310 lb. and costs about £ 392. This tractor

is easy to drive, and it may be used for cultivating in vineyards; it has been tested for this purpose at Montpellier, in vineyards near the National School of Agriculture.

5) Two English SAUNDERSON (1) tractors entered by the Paris General Omnibus Company. They are of 10 and 20 HP. and the Company proposes to make them in France.

6) The tractor made by M. H. DIMPRE, 35, Rue du Banquier, Paris, with a 40 H.P. engine. This tractor has the appearance of a motor lorry (Fig. 2 p. 1218.).

7) the "Aurore" tractor built by M. M. FOURNIER, of Levallois-Perret (Seine), whose engine drives the 4 equal-sized wheels. By removing

Fig. 3. — CLEVELAND tractor.

the horizontal chain drive to the front axle, the machine becomes a tractor with 2 driving wheels.

8) The "Motoculteur" of the "SOCIÉTÉ LA MOTOCULTURE FRANÇAISE" (2) which either works with rotatory implements or as a direct tractor.

9) the motor plough of MM. TOURAND-LATIL, of Suresnes (Seine) (3).

Among the American-made machines the author quotes: —

1) The "Cleveland" tractor (CLEVELAND TRACTOR C<sup>y</sup>, Cleveland, Ohio) presented by the ALLIED MACHINERY CO. of France, 19, rue de

(1) See *R.*, June, 1918, No. 678. (*Ed.*)

(2) See *R.*, January, 1918, No. 84. (*Ed.*)

(3) See *R.*, August 1917, No. 753. (*Ed.*)

Rocroy, Paris. This chain track tractor (Fig. 3) designed by Mr. R. H. White, is driven by a 20 H.P. engine; its dimensions are: — length 8 ft., width 4 ft. 1 in., height 5 ft. 3 in.; it weighs 3 344 lb. Each chain track is 7 in. wide and a length of 4 ft. 1 in. touches the ground; the distance between the axes of the chain wheels is 38 in. The frame, 12 in. above the ground, is mounted on springs. It can move up to 3 miles an hour and its smallest turning radius is under 6 ft. In the latest models the chain wheels and rollers are cased in.

2) The GRAY tractor (1), presented by the AMERICAN TRACTOR CO.,

Fig. 4. — HART PARR tractor.

11, Avenue du Bel-Air, Paris. This 30 H.P. tractor is sold at approximately £ 678.

The *Génie Rural* (No. 83) gives the following information about this tractor: — The GRAY tractor belongs to the type of tractor with a single, very broad driving wheel. That of this tractor is 51 in. wide with a diameter of about 59 in. The fore-carriage, mounted on a pivot-bearing, has wheels with a diameter of 37 in. and a width of 9 in. The tractor is 14 ft. long, 6 ft. 3 in. broad and 5 ft. high; it weighs 5 040 lb. The 4 cylinder WAUKESHA motor of 113 mm. bore and 170 mm. stroke runs at 850 revolutions. The BENNETT carburettor and the regulator are enclosed. The magneto and gas controls are fixed on the steering wheel. The driving wheel is connected by two symmetrical chains enclosed in oil baths.

(1) See *R.*, January, 1918, No. 81. (*Ed.*).

There are two speeds forward (2 and 3 miles per hour) and a reverse (2 miles per hour).

3) The "Hart Parr" tractor (Fig. 4, p. 1220), entered by the BUTTEROSI SYNDICATE, 148, avenue Malakoff, Paris, is driven by a single-cylinder vertical engine of the pilon type, of 250 mm. bore, 250 mm. stroke, and developing 35 H.P. at 500 revolutions per minute; cooling is by oil circulation. The front wheels, very close together, are 3 ft. 3 in. in diameter; the rear wheels, 6 ft. in diameter and 14 in. wide, are of cast steel with a grooved tyre; the arched grips are bolted on the grooves and project beyond the edge.

Fig. 5. — GALLOWAY tractor.

The Hart Parr tractor has two speeds, 9 515 and 12 452 ft. per hour, and its total weight is 11 440 lb.

According to *Le Génie Rural*, the Hart Parr tractor is composed of 300 different pieces, or 500 to 600 pieces less than all the other similar machines in existence. This great simplicity lessens wear and the risk of disastrous breakages during the working season.

4) The 2 CASE (1) tractors, entered by the CASE COMPANY, 251, rue du Faubourg St. Martin, Paris: one 18 H.P. tractor and one of 25 H.P.

5) The 20 H. P. MOGUL (2) tractors and the 20 H. P. TITAN (3), entered by the COMPAGNIE INTERNATIONALE DES MACHINES AGRICOLES, 155, rue Michel Bizot, Paris.

6) The 20 H. P. EMERSON tractor (4) entered by the CULTURE MÉCANIQUE Co., 175, rue de Flandre, Paris.

(1) See R., June 1914, No. 557; R., March and April, Nos. 274 and 753. — R., January 1918, No. 81. (Ed.). — (2) See R., June, 1916, No. 670. — R., 1917, Nos. 274, 753 and 1051. — (3) See R., 1917, Nos. 274 and 1051. — (4) See R., June, 1916, No. 670 — R., 1917, Nos. 274, 753 and 1051. (Ed.).

7) The 16 H. P. HAPPY-FARMER tractor (1) (sale price £420) and the 24 H. P. PARRETT tractor (1) (sale price £ 800), both entered by Messrs GASTON, WILLIAMS & WIGMORE, 1 rue Taitbout, Paris.

8) the GALLOWAY tractor (Fig. 5), entered by the ETABLISSEMENTS DE LACOUR ET FABRE, 4, avenue de Villiers, Paris. This tractor is driven by a 4 cylinder, vertical WAUKESHA engine, of 89 mm. bore and 133 mm. stroke developing 20 H. P. at 1 100 revolutions per minute The carburetter

Fig. 6. — NEVERSLIP tractor.

can be used for burning petrol or paraffin. The first model introduced into France is interesting for several details : — the engine is cast solid with the working parts and enclosed in a case ; the driving wheels are chain-driven and are 58 in. in diameter with tyres 14 in. wide. The central-sprung front axle, can deviate greatly compared with the back axle ; the front wheels are 36 in. in diameter with 5 in. tyres. The machine is 12 ft. 4 in. long,

(1) See R., January 1918, No. 81. (Ed.).

77 in. wide and 73 in. high; its total weight is 4 983 lb. of which 1 390 lb. are supported by the front axle and 3 593 on the back axle.

9) the **MOLINE** tractor (1) of the **MOLINE PLOW CO.**, 150 bis, quai Valmy, Paris; 2 machines were entered to show the improvements effected.

10) The **NEVERSLIP** tractor (Fig. 6), entered by Mr. A. W. **PIDWELL**, 19, boulevard Malesherbes, Paris. This tractor runs on the **NEVERSLIP** chain track. The 4 cylinder vertical engine (102 mm. bore and 152 mm. stroke) develops 25 H.P. at 850 revolutions per minute. The 2 forward speeds give 0.87 and 2.73 miles per hour and the reverse 1.49 miles per hour.

Each chain tread is 12 in wide and a length of 5 ft. is in contact with the soil. The machine is 9 ft. 6 in. long, 5 ft. 4 in. wide and 6 ft. without the shelter-roof and 9 ft. 5 in. with it.

11) 2 **AVERY** tractors (2), entered by Mr. T. **PILTER**, 24, rue Alibert, Paris; the 16 H. P. model costs £436 and the 25 H. P. model £660.

12) The 25 H. P. **BULL** tractor (3) entered by **SCHWEITZER & Co.**, 86 rue de Flaudre, Paris,

13) Two **ROCK ISLAND** tractors (4) of 16 H. P. (sale price £572) and 20 H.P. (cost, £740) and one 25 H.P. **LITTLE GIANT** tractor (5) (cost £900), entered by the **SOCIÉTÉ DES MACHINES AGRICOLES R. I. P.**, 60, avenue de la République, Paris.

14) The **MACCORMICK** tractor (20 H. P. Titan tractor) entered by Messrs **R. WALLUT & Co.**, 168, boulevard de la Villette, Paris.

II. — *Le Génie Rural* describes some of the most interesting machines entered for the Noisy-le-Grand trials and gives numerous figures.

**1146 - The Production of Agricultural Material and the Maximum Prices for Agricultural Machinery and Implements, in France.** — I. **MARIS-BESNARD**, in the *Bulletin mensuel de la Chambre Syndicale des Constructeurs de Machines Agricoles de France*, No. 4, pp. 169-175 + 1 Table. Paris, June, 1918. — II. *Feuille d'Informations du Ministère de l'Agriculture*, Year XXIII, No. 29, pp. 9-10 + 3 Tables. Paris, July 16, 1918.

The results of an inquiry made by M. **MARIS-BESNARD**, President of the "Chambre Syndicale des Constructeurs de Machines Agricoles de France".

The author thinks that, in order to estimate the French output of agricultural material, the number of workmen employed in French works must be used as a basis because, according to the evidence available, it can be shown that the market value of the products of a manufactory divided by the number of workmen gives a market value per workman that agrees very closely for similar industries with equal equipment.

For a large number of manufacturies this figure is 6666 francs (about £ 264.14s). One manufacturer who is best equipped and works in series, can arrive at 20 000 francs per workman. With smaller firms a figure slightly less than 6000 fr. is arrived at.

The "Chambre Syndicale des Constructeurs de Machines Agricoles de France" unites 410 firms making machinery, tractors, agricultural implements, appliances for dairying and agricultural industries. **DEBRAY'S**

(1) See R., 1917, Nos. 941 and 1051. — (2) See R., Aug., 1917, No. 753 — (3) See R., Sept., 1915, No. 953 and R., 1917, Nos. 274 and 1051. — (4) and (5) See R., 1917, No. 1051. (Ed.)

yearbook of Agricultural Construction mentions 1500 small firms making ploughing implements with 2 or 3 workmen, and which altogether represent about 1500 workmen.

Besides this there are thousands of workmen, farriers, smiths and ploughwrights that buy parts of the machines and assemble them. Their production can be estimated from the quantity of material supplied to them.

The author summarises in table-form the chief elements of French pre-war construction, using as basis documents and information supplied by the more important makers. No mention is made of the production of machines for mechanical cultivation — tractors, windlasses, etc. — which, in an embryonic stage before the war, is now undertaken by 22 firms, forming part of the Syndicate, and able to produce thousands of machines annually.

This table shows that the number of Brabant ploughs made in France in 1913 was 40 000 (64 syndicated firms) while that of various ploughs was 200 000 (2 000 small makers); the number of cultivators, harrows, rakes, was 150 000, and that of rollers was 50 000; 6 000 machine drills and manure distributors (10 firms) and 12 000 drills (11 firms) of various types were made; 5 firms made 10 000 mowers, and 7 made 3 000 harvesters and binders; 3 000 threshing sets were made by 48 firms; the number of agricultural motors made rose to 2 800 for 21 firms and 3 200 for the non-syndicated firms; 25 firms made 40 000 pumps; 27 makers made fixed farm machinery (root-choppers, mills, sifters, etc.) to the number of 230 000; the number of presses and apple-pounders, etc., rose to 180 000; 30 000 dairy appliances were made in 1913; about 100 firms made various types of implements, etc.

The production could be increased by 15 to 20 %, on taking into account about a thousand small, non-syndicated firms employing 2 or 3 workmen. The table also shows the tonnage produced (129 350 metric tons) and its market value (132 180 000 fr.).

II. — The French Minister of Agriculture has given his approval to the list of maximum prices for agricultural implements and machinery, proposed by the presidents of the "Chambre syndicale des constructeurs de machines agricoles", the "Chambre syndicale du commerce des machines agricoles", the "Consortium des fabricants de machines d'agriculture" and the "Consortium des industriels de la ferrure".

The maximum prices thus fixed for French and foreign-made machines respectively are : —

750 and 775 fr. for 1-horse mowers; 850 and 875 fr. for 2-horse mowers; 1150 and 1175 fr. for reapers cutting 49 in.; 1175 and 1200 fr. for reapers cutting 53 in.; 1215 and 1240 fr. for reapers cutting 59 in.; 2275 and 2300 fr. for binders cutting 59 in.; 2400 fr. for foreign-made binders cutting 83 in. (on account of increased freights, the delivery price of foreign-made binders includes an increase of 400 fr., that of foreign reapers 200 fr., and that of foreign mowers 150 fr.); 530 fr., 545 fr., and 565 fr. for French horse-rakes with 24, 26 and 28 teeth; 485 and 510 fr. for foreign horse-rakes of light type with 26 to 32 tines; 975 and 1100 fr. for tedders 96 in. wide; 950 and 975

fr. for tedders 71 to 96 in. wide ; 675 and 760 fr. for fork tedders (6 forks with 4 tines). The maximum price for sisal and manilla binder twine is fixed at 5.65 fr. the kg.

As regards all-metal ploughs (save those specially made for tractors), the maximum price has been fixed at 4 fr. the kg. for those weighing up to 110 kg.; at 3.75 fr. the kg. for those from 110 to 150 kg.; and at 3.50 fr. the kg. for those weighing more than 150 kg. For weeders, scarifiers, with steel frames and rigid or spring tines, the maximum price is 2.65 fr. the kg.; for metal harrows, 2.50 fr. the kg.; for 1-row hoes, 4 fr. the kg.; for hoes for more than one row, 3 fr. the kg.; for steel-sheet rollers, 1.40 fr. the kg. and for those in cast iron, 1.30 fr. the kg.

**1147 - Exports of Implements, Twine, Tractors and Gas Engines from the U. S. A. for the Period 1915 to 1917.** — *Farm Implement News*, Vol. XXXIX, No. 14, p. 21 + 1 Table. Chicago, April 4, 1918.

The exports of implements, tractors and gas engines from the U. S. to other parts of the world from 1915 to 1917 inclusive is shown in the following Table:—

**1148 - The Price of Binder Twine in the U. S. A., in 1918.** — *Weekly News Letter*, U. S. Dept. of Agriculture, Vol. V, No. 42, p. 4. Washington, May 22, 1918.

The prewar price for sisal averaged about 7 cents per lb. It was 7 ½ cents landed at ports of entry in June, 1916. In July of the same year, it was increased to 10 cents at which price it remained till December, 1916, when it rose to 16 ½ cents in March, 1917. In August 1917, it reached 19 cents at Gulf ports and 19 ¼ cents delivered at New York.

The cost of binder twine from sisal and other sources has been officially fixed for 1918 at 23 cents f. o. b. factory for 500 ft. twine, other grades being in proportion. The wholesale price is slightly higher to allow the dealers a fair profit. An ample supply of binder twine was assured for the harvest.

1149 - **The Jean Bache Vineyard Tractor.** — RINGELMANN, M., in the *Bulletin de la Société d'Encouragement pour l'Industrie Nationale*, Year CXVII, Vol. CXXIX, No. 3, pp. 565-566 + 1 Fig. Paris, May-June, 1918.

So that the tractor can pass between the lines of vines planted from 59 to 79 in. apart after the end of May, when the branches tend to cross, M. BACHE suggests the use of the machine A (see Figure), mounted on 3 wheels, of which 2, the front wheel *a* and the driving wheel *m*, could pass in the middle of the space *y' y'* which would be turned over by the plough *C*, whilst the third wheel *r*, on the left at the back, would pass in the space *yy'* and would only serve to maintain the balance of the machine. The third wheel might be loose on its axle so that its tyre (like that of the wheel *m*) would

Diagram of M. JEAN BACHE's vineyard tractor.

always run exactly in the centre of the space *yy'* between the rows of vines.

The greater part of the weight of the engine would be carried by the broad-tyred wheel *m*; the axle joining the wheels *r* and *m* would be elbowed, forming a sort of bridge *n* at least 59 in. high that could pass over the branches of the row of vines *y'* without harming them. Under these conditions the machine would have to turn to the left, as is always done with animals in the vineyards of southern France. As the space between the rows should be cultivated over its whole width in one turn, to facilitate turning 2, 3 or even 4 can be passed over on the headland, being cultivated afterwards.

The first model of the DESSAULES tractor (1) tried by the author in

(1). See R., January, 1918, No. 81 and R., March, 1918, No. 331. (Ed.)

1917 at Noisy-le-Grand, France, is similar in principle, save, that, in the rear, there is a second balance wheel  $r'$  symmetrical to the wheel  $r$  relatively to the driving wheel  $m$ , so as to provide for the transverse stability of the tractor.

**1150 - Rotary Harrow Attachment for Sulky and Multiple Gang Ploughs.** — POTTER, P. B., in the *Scientific American*, No. 22, p. 502 + 1 Fig. New York, June 1, 1918.

The rotary harrow described consists of a single gang of closely spaced spading discs. Each disc is made up of a number of sharp, steel blades, which are narrow and have a curved and twisted shape.

As the discs roll along, the blades stab and slice the furrow to pieces, and as there is a considerable number of blades, the surface is left with a fine even mulch. There is a lever for regulating the depth and a spring for adding pressure to the blades. As the discs have rather a revolving action than a dragging one, there is only an increase of 7 to 10 % in the draught on the plough. The attachment is made to clamp tightly to the plough frame and is readily adjustable in any direction ; it can be purchased for the single-bottom sulky or the multiple-bottom engine gang.

As the soil is freshly ploughed, it is more easily pulverised, provided the ploughing has been done under the right conditions.

**1151 - The Production of Groats and Oatmeal.** — *The Implement and Machinery Review*, Vol. XLIV, No. 518, p. 182 + 2 Figs. London, June 1, 1918.

Description of an oat milling plant, with figures showing the arrangement of the plant in a simple building, according to the plans of A. R. TATTERSALL & Co., milling engineers, 75D, Mark Lane, London.

Before milling the oats must be thoroughly dried, either in an ordinary kiln heated by coke, or by special oat-drying apparatus (which is preferred in some cases).

The dry oats are elevated automatically from the kiln floor and deposited in a bin ready for cleaning. From this bin the oats fall by gravitation into a special separator and cleaner, which delivers the grains sufficiently cleaned for treatment in the mills. From the cleaner, the oats are elevated and drop into a bin from which they fall to the shelling mill. This mill is fitted with stones of large diameter, fixed horizontally to a vertical shaft, which loosen the outer cuticle or shell of the grain ; the material is removed automatically to a reciprocating sieve, which eliminates any flour or meal made in the shelling process, and the overtails of this sieve are passed through a blower or aspirator for removing the loose shells. The groats are elevated to another bin, also placed over the shelling bin, to repass the stones, when a second separation is made on the sieve and blower. The shelled oats or "groats" next fall into a hopper fixed over the grinding mill, of the "India" pattern, fitted with stones of a special texture suitable for reducing the groats into fine meal as may be required. Following this the flour passes into a double vibrating sifter in conjunction with another blower for removing the fine particles of husk which may be still left in the meal.

This is a type of plant much favoured in Ireland, which country is now a rapidly increasing producer of oats and oatmeal.

*Oat-milling plant of TATTERSALL & Co.*

1152 - **The Scott Process and Plant for Drying Potatoes.** — *The Implement and Machinery Review*, Vol. XLIV, No. 518, pp. 184-186 + 4 Figs. London, June 1, 1918.

In the SCOTT process the potatoes are delivered into a washer, which consists of an inclined trough fitted with a revolving spiral. The spiral is

Fig. 1. — Scott drying plant: Plan.

Fig. 2. — Scott drying plant: Elevation.

driven slowly and forces the potatoes along into an elevator boot. At this point is fitted a device for separating the stones, adjusted so as to float the

tubers but not the stones. A stream of water runs continuously in a contrary direction to the potatoes and so washes off all dirt.

As is shown in the appended figures, the potatoes are now elevated into a *peeling machine*, which consists of a rotating cylinder, the interior of which has an abrasive surface which rasps the skin from the tubers, the peelings passing to the bottom of the containing tank. The rotating cylinder is slightly inclined to induce the potatoes to travel forward. The peeling operation is also carried out under water; the resulting sludge, when filtered and dried makes an excellent cattle and poultry food

After peeling the potatoes are conveyed to a *slicing machine*, the buckets of this second elevator being perforated to complete the draining of the

Fig. 1. — SCOTT drying plant: end view.

potatoes. The slicing machine consists of a rapidly revolving disc fitted with cutting knives. The potatoes are fed up to these knives by means of a suitable hopper, and from this point they pass in fine slices into a *drying machine* over a spreading device which distributes them evenly.

The drying machine is in 2 portions. In the upper part or steaming chamber, the potatoes are constantly in contact with steam, which is led into this portion by suitable pipes. The lower and larger portion is the drier

proper. This consists of a closed chamber, containing a number of endless moving bands which carry the charge through the chamber. The slices are spread on the top band and travel along to the far end of the machine, when they drop on to the next lower band, and are carried to the feeding end of the chamber. This forward and backward process is repeated until the lowest band carries them right out of the chamber, dry, and deposits them at some point ready for grinding.

The actual drying is carried out by hot air. The air is heated by drawing it over steam-heated pipes by means of large fans which force it to perform a continuous circuit through the heater, into intimate contact with the steamed potato slices, then back through the heater, and so on.

An extraction fan constantly withdraws a small portion only of the most saturated air, and this is replaced by fresh air at a convenient spot near the heating pipes. In this way great economy is effected in steam consumption, as partly used air is directed into the drying chamber again and again, so obviating the necessity for heating up a complete supply at each journey through the drying chamber and thus avoiding the loss of heat in the exhaust air.

Throughout the whole of the operations the material is never handled, and labour is thus reduced to the bare handling of the potatoes on reception. By the provision of suitable silos in large plants even this operation can be made of insignificant importance.

Where steam is not available for heating, the makers provide a direct-fired air heater which can burn any kind of fuel.

Messrs. SCOTT & SON Ltd., 72 Oxford St., London, make all the plant necessary for drying potatoes preliminary to milling, but do not manufacture the milling plant. However, any machine suitable for fine grinding, fitted with fine screens, would meet requirements, such as a CARTER disintegrator, fitted with a sifting reel and bagging attachment.

The SCOTT drier can also be used for other vegetables as well as fruits. The machine costs more than ordinary driers, but it more than repays its extra cost in the economy of labour and fuel.

**1153 - Peanut Decorticators.** — See No. 1160 of this Review.

**1154 - Machines for the Recovery of Grape Stones for the Production of Oil.** — VENTRE, J., in *Le Progrès Agricole et Viticole*, Year XXXV, Vol. LXX, No. 29, pp. 54-61 + 2 Figs. Montpellier, July 21, 1918.

For the satisfactory recovery of the stones from grape residue, the author shows that a sifter is necessary for large works dealing with 22 000 to 44 000 lb. of residue a day, while a cylindrical sorter suffices for smaller establishments.

The sifter described by the author consists of a wooden frame supporting a sheet of galvanised iron wire gauze with an 8 mm. mesh sloping at 15 to 18°. The frame is attached to the bed by carriage-springs 6 mm. thick and strengthened at their lower part to avoid breakage. The frame is moved to and fro by a cranked shaft at the rate of about 250 oscillations per minute. The sifter is about 9 ft. long of which 6 ft. 6 in. is used, the 2 ends being

strengthened with iron so that the residue will not break the gauze in falling on it ; it is 31 in. wide. The residue arriving at the upper part of the frame moves along as the result of its own weight and the oscillating motion. The sifting forces the residue to turn, thus shaking and scraping it on the gauze. The stones fall through with a little pulp that can easily be separated by cleaning in the winnowing-machine. Some  $\frac{3}{4}$  to 1 H.P. are required to drive the machine, which can treat from 22 000 to 44 000 lb. of residue per day, separating from 6 600 to 8 800 lb. of stones. The sifter deals equally well with wet residues from diffusion vats or distillation apparatus.

The cylindrical sorter consists of a cylinder covered with galvanised-iron wire gauze with an 8 mm mesh ; its diameter is 22 in. and its length 6 ft. 6 in. To strengthen it and prevent the gauze from bulging the cylinder is enclosed with 5 iron hoops (1 at each end and the others every 20 inches) fasted to the central axle with iron ties and to one another with hoop-iron. The cylinder is supported by 2 iron-shod poles carrying a bearing in which runs the central axle. The cylinder is inclined at about 12.5 % to the horizontal to speed-up the work ; it runs at 35 to 40 revolutions a minute. Two men are required, one to turn the cylinder, the other to feed in the residue. Some 880 lb. of stones may be obtained in a day, but as the machine is slow and the work is not so well done as in the sifter, it should only be used with dried residue. The two machines are not complicated, and they are easy to make. With them both commercial men and vine growers can rapidly recover the stones without waiting for fermentation to start in the residue, coagulating the pectic matter, which would have the double disadvantage of hastening the resinification of the fatty acids of the oil and also of favouring the retention of a large quantity of pips in the pulp.

The stoned residues can be at once ensilaged for feeding live stock, especially sheep.

#### 1155 - Review of Patents.

**TILLAGE MACHINES AND IMPLEMENTS.** — *Canada*: 182788 Wheel plough ; 182804 Grubbing implement.

*France*: 486735 The use of the BAUDRY motor-binder (1) as a motor plough, etc. ; additions Nos. 20598 and 20599 ; 487693 Plough consisting of 2 motor-driven, identical and juxtaposed screws.

*United Kingdom*: 116366 Harrow ; 116795 Device for automatically raising the frame of a motorplough or cultivator.

*United States*: 1267502-1268893 Ploughs ; 1268060 Stalk cutter ; 1268150-1268861 Harrows ; 1268319 Combined harrow and roller ; 1268823 Plough cleaning attachment ; 1269028 Motor driven agricultural machine ; 1269138 Wheelplough ; 1269166 Wheeled disc plough ; 1269484 Earth scraper ; 1270087 Land roller ; 1270180 Agricultural implement ; 1270299 Disc harrow ; 1270317 Rotary harrow ; 1270525 Traction plough ; 1270627 Motorplough.

(1) See R. July, 1918, No. 309, patent No. 486735. (Ed.)

**DRAINAGE AND IRRIGATION.** — *Sweden*: 42852 Watering device for field or garden; 42955 Ditching machine.

*Switzerland*: 78751. Ditching machine.

*United States*: 1268148 Ditching attachment for turning plough; 1270597 Corner finisher for irrigation.

**MANURES AND MANURE DISTRIBUTORS.** — *Sweden*: 42643 Feeding device for fertiliser distributor; 42675-42887 Manure spreaders; 42922 Liquid-manure spreader.

*United Kingdom*: 116758 Manures obtained by treating with yeast peat and farm or agricultural refuses and added with phosphoric and potassic materials.

*United States*: 1267563 Broadcast spreader; 1269189 Method of recovering fertilising material from tannery waste liquids; 1270070 Fertiliser distributor; 1270071 Feeding mechanism for fertiliser distributor.

**DRILLS AND SEEDING MACHINES.** — *Sweden*: 42781 Device for drills; 42853 Potato planter.

*United States*: 1267397 Potato seed cutting machine; 1267583 Peanut planter; 1267713 Check row transplanter; 1267762 Landmarker for planters; 1268291 Check row planter attachment; 1269451 Maize planter; 1269591-1270577 Planters; 1269877 Hand seed planter; 1270109 Attachment for grain drills.

**VARIOUS CULTURAL OPERATIONS.** — *Netherlands*: 2545 Temporary, portable, glass-roofed shelter for young plants.

*Sweden*: 42983 Device for horse-hoe; 42985 Hoe with hollow handle provided with a device for sowing forage seeds; 42986 Hand hoe.

*Switzerland*: 78750 Hand-hoe.

*United Kingdom*: 116175 Hand hoe, rake, marker and clod chopper combined; 116525 Combined rake and hoe.

*United States*: 1267425-1268117 Shield attachment for maize planters; 1267518 Cultivator shovel; 1268042 Cotton chopper; 1268687 Potato cultivator; 1269129 Weeding machine.

**CONTROL OF DISEASES AND PESTS OF PLANTS!** — *Canada*: 183160 Animal trap.

*New Zealand*: 38637 Weed eradicator and digger.

*Sweden*: 42561. Apparatus for destroying injurious insects.

*United Kingdom*: 115755 Animal trap; 116762 Device for raising and supporting vegetation whilst sprayed underneath with a sprayer.

*United States*: 1267391-1268166-1269596 Animal traps; 1268127 Insect catcher; 1268660-1269334 Boll weevil destroyers; 1268992 Quackgrass digger.

**REAPERS, MOWERS AND OTHER HARVESTING MACHINES.** — *Canada*: 182878 Binder mechanism.

*New Zealand*: 39806 Fruit picker.

*Sweden*: 42528 Divider for mower; 42723 Fruit picker; 42923 Grain saving attachment for harvester.

*Switzerland*: 78753 Binding apparatus.

*United Kingdom*: 116191 Rubber tapping knife; 116300 Motor driven sugar cane harvesting machine; 116522 Flax pulling machine.

*United States* : 1267559 Kafir corn header ; 1267614-1268902-1269550-1270202 Peanut harvesters ; 1267938 Shock binder ; 1268169-1269516 Shocking machines ; 1268302 Attachment for harvester-header ; 1268345-1268384 Maize huskers ; 1268698 Adjusting device for harvesting machine ; 1268882 Attachment for sweep rake ; 1269161 Elevator support for harvester ; 1269393 Sweep rake ; 1269522 Combined harvester ; 1269742 Seed harvesting machine ; 1269781 Binder attachment ; 1270016 Butt adjuster mechanism for grain binder ; 1270487 Gearing for mowing machine ; 1270488-1270489-1270490-1270491 Mowers.

**MACHINES FOR LIFTING ROOT CROPS.** — *Denmark* : 23081-23098 Turnip harvesters.

*Sweden* : 42500 Continuous horizontal conveyer for attachment to beet diggers ; 42704 Beet topping machine ; 42822 Beet digging and topping machine.

*United Kingdom* : 116120 Potato digger and harvester.

*United States* : 1267692 Potato separator ; 1268085-1269789 Beet harvesters ; 1268388-1269371 Beet toppers ; 1270503 Beet topping device for beet harvesting machine.

**THRESHING AND WINNOWER MACHINES.** — *Canada* : 182968 Threshing machine ; 183056 Vacuum grain loader and cleaner.

*United Kingdom* : 115951 Apparatus for the separation and dressing of seeds and grain.

*United States* : 1268857 Conveyer attachment for threshing machine ; 1269033 Feeder for threshing machine ; 1269109 Threshing machine ; 1269211 Pea viner.

**MACHINES AND IMPLEMENTS FOR THE PREPARATION AND STORAGE OF GRAIN, FODDER, ETC.** — *Canada* : 183240. Stacker feed mechanism.

*New Zealand* : 38870 Flax stripping machine.

*United Kingdom* : 116178 Baling press ; 116238 Hay collecting and cocking machine which may be provided with threshing drum for separating the seeds from the hay ; 116333 Scutching apparatus ; 116378-116789 Hay cocking machines.

*United States* : 1268122 Hay and bundle loader ; 1269358 Grain transferring device ; 1269435 Automobile truck ; 1270123 Hay loader ; 1270145 Baling press.

**FORESTRY.** — *Canada* : 182804 Grubbing implement.

*France* : 487366 Machine for felling and cutting trees.

*Sweden* : 42635 Small brush bunding machine.

*United Kingdom* : 116015 Portable saw for felling and cutting trees ; 116783 Sawing machine for cutting felled timber.

*United States* : 1270010 Method of treating decayed spots and cavities in wood.

**TRACTION AND STEERING OF AGRICULTURAL MACHINERY.** — *Canada* : 182695 Coupling for hay racks.

*France* : 486496 CHAPRON agricultural tractor (1) improvement, addition No. 20578 ; 487763 Agricultural tractor.

(1) See R. June, 1918, n° 682, p. 747, patent 486455 (for this number read No. 486496).  
(Ed.)

*New Zealand*: 39892 Windmill.

*United Kingdom*: 116112 Transmission gearing for motorploughs and motorvehicles; 116141-116142-116143-116144-116145-116164 Endless track vehicles; 116180 Tractor.

*United States*: 1267503-1267525-1267825-1267986-1268034-1268324-1270480-1270531 Tractors; 1267768 Traction engine; 1268116 Tractor attachment for motor truck; 1268417 Automobile traction wheel attachment; 1268493-1270252 Tractor wheels; 1268517 Traction tread device for tractor wheels; 1269293 Device for attaching ploughs to vehicles; 1269609 Steering device for traction engine; 1269755 Tractor gearing.

FEEDING AND HOUSING OF LIVESTOCK. — *Canada*: 183152 Animal holder.

*United Kingdom*: 115062 Horse blanket; 116318 Pig and poultry food from stomachs of slaughtered animals; 116357 Processes for producing a meal or flour from brewer's and distillers' grains.

*United States*: 1269346 Cattle stanchion; 1269943 Hog trough.

POULTRY FARMING. — *Canada*: 182779. Drinking fountain.

*United Kingdom*: 116318 Pig and poultry food from stomachs of slaughtered animals; 116560 Door opening device actuated by the weight of a fowl.

*United States*: 1267426 Incubator; 1268347 Egg case package; 1269874. Poultry drinking fountain; 1270756 Egg turner.

API CULTURE. — *Denmark*: 23110 Bee feeder.

*United States*: 1270507 Bee hive.

INDUSTRIES DEPENDING ON PLANT PRODUCTS. — *Canada*: 182822 Vegetable slicing and shredding machine; 183142 Flour sifter; 183179 Sap spout.

*Switzerland*: 78752 Drying apparatus.

*United Kingdom*: 116167 Fruit cleaning apparatus; 116233 Bottling machine; 116401 Sugar cane mill; 116521 Process of extracting sugar from canes; 116606 Apparatus for drying fruits, vegetables, seeds, fibres, etc.

*United States*: 1267419 Sugar refining apparatus; 1267655 Fruit drier; 1267776-1268398-1270733 Tobacco stemming machines; 1269412 Fruit and vegetable drier; 1269843 Method of canning maize; 1269966 Apparatus for the washing of raisins and the like.

INDUSTRIES DEPENDING ON ANIMAL PRODUCTS. — *New Zealand*: 39782 Meat, etc., preservation by fumigation.

*United Kingdom*: 115009. Tanning process.

DAIRYING. — *Canada*: 182683 Churn.

*New Zealand*: 39856 Milking machine.

*Sweden*: 42636. Separator device; 42640 Discharge regulator for separator; 42783 Device for preventing excessive foaming in a centrifugal separator; 42854 Churn easily convertible into a separator; 42924 Device for joining cups and pipes in milking machines.

*Switzerland*: 78786 Churn mechanism.

*United Kingdom*: 115717 Churn; 116048 Milkcan.

*United States*: 1267920 Cheese press; 1268766 Churn; 1268792 Sani-

tary milk pail; 1269015-1270091 Milking machines; 1269348 Cream skimming device; 1270429-1270473 Pulsator for milking machines.

FARM BUILDINGS AND EQUIPMENT. — *Canada*: 182886 Gate; 182994 Wire stretcher; 183184 Ventilator mechanism.

*United States*: 1267863 Silo; 1268948 Fence gate.

VARIOUS. — *Canada*: 183146-183214 Pumps.

*New Zealand*: 39913 Germination of seeds testing box.

## RURAL ECONOMICS.

**1156—Influence of a City on Farming.** — ARNOLD, J. K. and MONTGOMERY, F., in *U. S. Dept. of Agric. Bulletin. No. 678* (Office of Farm Management), pp. 1-24. Washington, D. C., May 7, 1918.

This bulletin gives the results of a study of the agriculture of Jefferson County, Kentucky, a locality which is influenced greatly by a moderately large and growing city, Louisville. In response to a favourable and increasing market for vegetables, an increasing area of land is being utilised for market gardening. The raising of such crops as potatoes and onions has been profitable, principally on account of exceptional marketing facilities. The raising of cereals while still important has declined. The city offers an expanding market for dairy products, but by means of railways and tramways the city is quickly and cheaply reached by dairy farms located a long distance out, where cheaper land and other favourable conditions enable the farmer to compete successfully in the dairy market. With the growth of the city, the extension of trolley lines and the improvement of highways, an increasing number of people occupied in the city are living in suburban towns and in the near-by country. All these factors combined created a set of conditions which brought about rapid changes in agricultural practice.

Old types of farms, once dominant, are now disappearing, and new types are organised to profit by the opportunities offered. Farms that were once profitable as large units, under an extensive system of agriculture, come to be relatively unprofitable under new conditions creating higher values for real estate.

These conditions are analysed in this study in order to arrive at an understanding of the underlying principles of farm organisation and practice in the area surveyed, to point out the more profitable types of farming and to show how some of the more successful farms are organised.

*Sources of information and basis of study.* — In the autumn of 1913 about 50 farms were visited and a detailed study was made of the leading crop enterprises. In 1915 another farm-management survey was made of 100 farms in this area, within 20 miles from Louisville, representing various types, in which the organisation and the business success of each farm were carefully studied.

*The City and the County.* — The city of Louisville, on the Ohio River, occupies an area of about 28 square miles, and reached in 1916 a population of 267 342.

The city market place is operated by an association of farmers and business men.

The rural population of Jefferson County, including unincorporated towns was 38 992, showing an increase of 42.4 % during the preceding 10 years. During the same period the city population had increased 9.1 %. These figures indicate a rapid growth of suburban population. Outside of unincorporated towns the increase was over 30 %. Seven per cent of the population in 1909 was foreign born and 32 % of mixed parentage.

There were in 1909 3 093 farms in the county, an increase in ten years of about 9 %. During the previous decade the number of farms under 100 acres in size had increased 17 %, while farms over 100 acres in size had decreased about 14 %. During the same period the area devoted to the raising of vegetables had increased about 29% and the area devoted to cereals decreased about 22 %. Within the county during the decade 1899 to 1909 there was a marked decrease in the production of market milk, while three adjoining counties farther out with railway communications had a marked increase in milk sold. The decrease in Jefferson county was 43 %, while the increase in three outside counties was about 232 %. Jefferson county had a large increase in the amount of butter and cream sold, which to some extent made up for the loss in market-milk production. Butter, however, is made in small quantities as a by-product on nearly all types of farms, so that the increase in this product can not be said to make up the loss in market milk production. The census figures further show a decrease in the number of dairy cows in Jefferson County and an increase in the three outside counties during the same period.

*Soil and climate.* — The soil in the northeastern part of the county is a clay loam similar in character to the bluegrass soils farther east. The southeastern part of the county has relatively the poorest quality of soil, besides a portion which is hilly or mountainous. Much of the region, however, might be termed river-bottom land.

The climate is typical of that found in the lower elevations of the south-central States. The winters are comparatively wet, the highest average rainfall coming in March. The dry season begins in July and ends in November. The average growing season extends about 186 days, 200 days during the year being available for field work.

*The farm practice.* — Several types of farming are found in a radius of 20 miles from the city, representing two general systems of farm practice, the extensive and the intensive. The farms practising the extensive system are found toward the eastern part of the county and become more nearly typical as the bluegrass region is approached. These farms usually are large or medium-sized. The rougher and stony parts are kept in permanent bluegrass pasture. Orchard grass and clover are grown in rotation with grain and potatoes. Live-stock enterprises, dealing chiefly with beef cattle, dairy cows, sheep, swine and horses, are important. Irish potatoes, which often take the place of maize as an intertilled crop on these general farms, commonly occupy 25 to 50 acres.

On the smaller farms nearer the city the farm practice is entirely dif-

ferent. Nearly all the tillable area of these farms is planted in field truck crops, a very small percentage being left for pasture. Much of the land is double-cropped.

*Relation of distance from the City to Type of Farming.* — Table I indicates the influence that distance from the city has on the type of farming. Receipts from such field crops as maize, wheat, hay, hogs, and stock cattle are grouped in this table under the head "receipts per cent from other sources".

TABLE I. — *Relation of distance from city to type of farm.*

Distance from city	Number of farms surveyed	Size of farm acres	Rent of land per acre \$	Receipts per cent		
				From truck and potatoes	From dairy	From other sources
8 miles or less. . .	25	102	11.85	68	10	22
9 to 11 miles. . .	18	221	5.59	35	12	53
12 to 14 miles. . .	24	256	5.37	34	20	46
15 miles and over. .	33	257	4.66	20	27	53
<i>All farms</i> . . .	<b>100</b>	<b>211</b>	<b>6.80</b>	<b>38</b>	<b>18</b>	<b>44</b>

*The small intensive farms near the city are the most profitable.*

The relation of size of farm to operating expenses per acre and to land earnings per acre, with growing distance from the city, is illustrated in Table II.

TABLE II. — *Relation of size of farm to operating expenses per acre and to land earnings per acre.*

Size of farm	Number of farms	Distance from city	Average area of improved land	Operating expenses per acre	Gross receipts per acre	Land earnings per acre	Labour income	Profit on investment
<i>Acres</i>		<i>Miles</i>	<i>Acres</i>	\$	\$	\$	\$	%
Less than 80	21	9	44	73	96	23	1000	7
80 to 159	25	12	121	36	45	9	800	5.6
160 to 299	33	13	212	15	20	5	100	4
300 and over	21	16	420	14	18	4	140	4
<i>All farms</i>	<b>100</b>	—	<b>199</b>	<b>32</b>	<b>42</b>	<b>10</b>	—	—

The main reason for low profits on the larger as compared with the smaller farms is that many of the larger farms are not doing intensive enough agriculture to meet the new conditions brought about by a large and growing city.

*Distance from the city a factor in the value of land.* — As has been pointed out the building of good roads, the extension of tram lines, and the nearness of the city have made much of the land in this section desirable for other than agricultural purposes. Such conditions make the average market value of land higher than it should be for agricultural use alone. This is indicated in Table III.

TABLE III. — *Influence of the nearness of the city on the value of land and rent.*

Distance from Louisville	Number of farms	Rent of land per acre	Value of land per acre
Less than 8 miles . . . . .	25	\$ 11.85	\$ 312
9 to 11 miles . . . . .	18	5.59	110
12 to 14 miles . . . . .	24	5.37	106
Over 14 miles . . . . .	33	4.66	95
<i>All farms . . .</i>	<b>100</b>	<b>6.80</b>	<b>158</b>

*The effect of land value and nearness to city on the use of manure and commercial fertiliser.* — To some extent large quantities of stable manure are used by truck farmers in the vicinity of Louisville. The availability of manure at a reasonable price is one of the limiting factors in profitable truck farming in the vicinity of the city as shown in Table IV.

TABLE IV. — *The effect of land value and nearness to city on the use of manure and commercial fertiliser.*

Value of land per acre	Number of records	Distance to Louisville Miles	Size of farm Acres	Rent per acre \$	Value of farm manure and commercial fertiliser per crop acre	
					Barn manure \$	Commercial fertiliser \$
Less than \$ 80 . . .	23	16	284	5.50	3.75	0.60
\$ 80 to \$ 150 . . .	34	13	250	6.60	4.50	0.70
\$ 151 to \$ 200 . . .	22	12	188	8.75	4.60	1.90
Over \$ 200 . . . . .	21	8	95	15.00	18.00	1.25
<i>All farms . . .</i>	<b>100</b>	<b>12</b>	<b>212</b>	<b>8.60</b>	<b>7.35</b>	<b>0.90</b>

*Comparative study of types of farms.* — The foregoing tables show that there is a tendency for the farms to be smaller and more intensive near the city, while the farms 15 to 20 miles out are larger and raise general crops — maize, wheat, rye, bluegrass — and keep various kinds of live stock, such as beef cattle, dairy cows, sheep and hogs. These enterprises are the sources of farm receipts, usually pretty well balanced between crops and live stock. Such farms may be classified as the "general mixed type". If dairying becomes a dominant enterprise, with 40 % or more of receipts from milk or milk products, the farm may be classified as a dairy farm.

If 40 % or more of the receipts come from potatoes alone the farm may be called a potato farm ; if from potatoes and truck a potato-truck farm. These classifications are shown in Table V.

TABLE V. — *Relation of type of farm to size of business and labour income.*

Type of farm	Number of records	Acres of improved land	Value of capital invested	Total operating expenses per farm	Labour income
General mixed. . . . .	39	270	\$ 34 700	\$ 3 667	\$ 126
Dairy . . . . .	22	205	27 782	3 686	441
Potato . . . . .	11	192	35 000	3 715	333
Potato-truck. . . . .	24	62	20 000	3 950	1 350
<i>All farms</i>	<b>96</b>	<b>195</b>	<b>30 084</b>	<b>3 738</b>	<b>520</b>

The potato-truck type of farming is by far the most profitable of the 4 groups. This fact undoubtedly accounts in large part for the tendency towards more intensive farming. It must not be concluded that the potato-truck farms grow only potatoes and truck or that potato farms grow only potatoes. Other enterprises such as maize, wheat, dairy cows, hogs and sheep, have a place of more or less importance on most farms of these types. So also many dairy farms and general mixed farms handle enterprises characteristic of the more intensive types. Location with reference to the city, the soil and the transportation facilities are the principal factors determining the organisation of the more profitable type of farms.

*Distribution of capital on farms of different types.* — Table VI shows the amount and distribution of capital on the types of farms included in this study.

TABLE VI. — *Relation of type of farm to distribution of capital on 96 farms in Jefferson County, Ky. (values are averages).*

Type of farm	Number of records	Total capital	Market value of real estate	Working capital	Investment in live stock	Investment in machinery	Cash to run farm	Investment in work stock	Value of dwelling	Value of other buildings
		\$	\$	\$	\$	\$	\$	\$	\$	\$
General mixed . . . . .	39	34 700	30 589	4 111	1 977	722	785	1 050	2 619	1 626
Dairy . . . . .	22	27 782	23 247	4 535	2 911	697	448	661	2 950	2 349
Potato . . . . .	11	35 000	31 406	3 594	1 358	769	1 100	923	3 545	2 002
Potato-truck . . . . .	24	20 000	17 511	2 489	847	620	698	697	2 062	946
<i>All farms . . .</i>	<b>96</b>	<b>30 084</b>	<b>26 198</b>	<b>3 859</b>	<b>1 986</b>	<b>691</b>	<b>706</b>	<b>844</b>	<b>2 660</b>	<b>1 707</b>

*Distribution of crop area.* — Table VII indicates that about 50 % of the crop area on the average truck and potato truck farms is used in growing truck and potatoes, crops which represent intensive farming. The remainder of the area is used for growing maize, hay and miscellaneous crops, principally for feeding the work horses, dairy cows and hogs.

TABLE VII. — *The distribution of crop area on different types of farm.*

Type of farm	Number of records	Crop area in farm acres	Per cent of crops area in							
			Maize	Slage	Potatoes	Wheat	Hay	Truck	Miscellaneous crops	Green manure crops
Potatoes . . . . .	11	133	17.9	3.4	24.9	16.2	12.9	3.5	8.8	12.4
Potato-truck . . . .	12	60	15.2	—	29.6	1.2	12.2	24.1	8.2	9.5
Truck . . . . .	12	45	16.6	—	13.1	1.3	12.7	39.9	13.5	2.9
Dairy . . . . .	22	82	26.0	9.1	5.7	7.3	15.7	2.4	28.8	5.0
General mixed . . .	39	160	27.2	0.9	8.6	17.9	21.4	2.4	14.9	6.7

The distribution of different classes of animals on the different types of farms is as follows :— On the intensive types dairy cows, poultry, and swine are comparatively more important, while on the more extensive types, stock cattle, horses, and sheep are relatively more important. On the more intensive types of farms growing potatoes and truck, there is relatively a large amount of unmarketable products which, without stock to utilise them, would be wasted. Dairy cows, swine and poultry utilise these as well as the permanent pasture, and thus are profitable when in proper proportion to other enterprises.

The important conclusions drawn from this survey are :—

1) For the area surveyed the small farm intensively cultivated is the most efficient and profitable.

2) The most profitable types found are those specialising in potatoes and truck.

3) Dairying combined with truck farming is profitable, but as a type it is gradually being pushed farther away from the city to cheaper land.

4) The general mixed type of farm, representing the extensive system and a high degree of diversity, is the least profitable in this area.

Descriptions of several farms illustrating types found in this section are appended.

## AGRICULTURAL INDUSTRIES.

1157 — Research on Malting and a New Process for the Reduction of Malting Loss. — NOWAK, C. A., in *Pure Products*, Vol. XIV, No. 5, pp. 219-223. New York, May, 1918.

The principal object of the method is to eliminate as much as possible the invisible loss, the loss by respiration, caused by the transformation of carbohydrates into CO<sub>2</sub> and H<sub>2</sub>O and to check the excessive growth of

INDUSTRIES  
DEPENDING  
ON PLANT  
PRODUCTS

[1156-1157]

the rootlet without retarding or preventing the full development of the acrospire. The annual invisible losses in United States breweries are estimated at over 2 million dollars.

A further object is to provide a malt high in acidity, specially adapted to the production of bottling beers. Moreover, this new method gives a malt which contains the principles necessary to yeast propagation, giving a healthy fermentation and constantly maintaining the yeast in strong condition.

The barley is sorted and cleaned in the usual manner, soaked in the steeping vats and aerated by passing air through the water, to which no lime or lime water is added, as this would neutralise the pre-existent acidity of the grain which it is the object of the method to preserve as much as possible. When the addition of lime is necessary, as in hot weather especially to prevent mould or premature decomposition of the steep water, chloride of lime should be added so that the steep water contains about 0.034 % of chlorine in solution.

After steeping, the barley at the flooring stage is sprinkled with a phosphoric acid solution containing not less than 0.1 % or more than 0.4 % acid, the concentration being dependent on whether the malt is to be used for brewing or distilling purposes. When the malt has reached the desired solution as judged by the development of the acrospire, not that of the rootlet, which may be delayed, it is put in the kiln.

The stimulating effect of the phosphoric acid upon the change within the grain is so marked that the flooring period may be shortened by 12 to 24 hours without there being any danger of obtaining a product poor in solution. This is a great advantage as the output of a malting plant may be greatly increased thereby.

The process requires no change in the equipment and produces a malt very rich in soluble extract and acidity. The high diastasic and peptic power of malt prepared thus is not due entirely to the action of the respective enzymes *per se*, but also partly to the hydrolysing action of the relatively strong acids on the peptones and carbohydrates. The comparative results are given of analyses of two malts prepared with the same barley, one by the ordinary method, the other by the new method. Malt treated with phosphoric acid gives about 1% more extract than untreated malt. The increase in acidity was 0.018 % of the total acid.

**1158 — The Capacity of Wheat and Mill Products for Moisture.** — STOCKHAM, W. L., in *Bulletin No. 120 of the North Dakota Agricultural Experiment Station*, pp. 97-131, + 10 Tables + 11 Diagr. Agricultural College, North Dakota, January, 1917.

The author has made a number of experiments on the influence of water on wheat and wheat products; the results are summarised as follows:—

1) The capacity or amount of water required to make a mixture of a given consistency of water and colloidal material is greatest when the component parts are in a state of equilibrium with each other.

2) The capacity of wheat and its products for atmospheric moisture and water increases as the physical equilibrium between the component particles is approached.

3) Wheat has a higher moisture capacity than any of its products. The natural capacity for water vapour of wheat and its products under the same conditions is as follows:— wheat 12.4 per cent, patent flour 11.31, bran 11.17, first clear flour 11.07, second clear flour 10.86, and shorts 10.5 per cent (the percentages of moisture are calculated on the dry weight of the samples at the beginning of the test). This is in the reverse order of their protein contents (the wheat excepted).

4) Starch prepared from patent flour has a higher capacity for atmospheric moisture than that from clear flour.

5) The capacity of wheat for atmospheric moisture is greater at zero than at higher temperatures, diminishing with increase in temperature. Above 60° C. it is dependent upon chemical changes which in turn are dependent upon the amount of moisture available. At the saturation point between 0 and 40°C. the theoretical limits are only one-third to one-half reached because of secondary changes produced by enzymes, bacteria and moulds.

6) Previously sprouted wheat absorbs both water and water vapour more rapidly than wheat in the natural state. It reaches its maximum sooner but does not reach as high a maximum as the normal wheat.

	Maximum moisture content Sprouted	Natural
Saturated atmosphere. . . . .	35.42 %	37.43 %
Immersed in water . . . . .	68.9	101.8

7) Wheat products have a more rapid rate of adjustment to modified moisture conditions than wheat and are more subject to secondary changes.

8) Germination does not take place from water absorbed from the atmosphere (condensation excluded).

9) The rate of change of the moisture content of wheat in the atmosphere or in water becomes slower as the maximum limits are approached.

10) In water (when growth does not take place) the capacity of wheat is greatest at zero, decreasing with increase in temperature until at approximately 60°C. hydrolysis begins. The rate of absorption is many times more rapid with the higher temperature. Before secondary changes have advanced noticeably a ten degree rise in temperature almost doubles the rate of absorption.

11) Secondary changes are nearly eliminated at zero. The losses are least at that temperature, amounting to only 5.5 per cent in 27 days. At 25° C. they amount to 23.4 per cent in 5 days.

12) The absorptive capacity of the wheat varies inversely as the water absorbing power of the flour produced from the same wheat, and as a rule inversely to the protein content.

13) The durumms are similar to hard red spring wheat samples of the same protein content in rate and quantity of water absorbed.

14) Pressure upon a water wheat mixture where either may change in volume at the expense of the other does not appreciably affect the rate

or amount of water absorbed by wheat where the secondary changes are eliminated or are slight.

15) Pressure upon the wheat itself diminishes markedly its capacity and rate of absorbing water.

16) A temporary variation of 5 per cent in the absorptive capacity of a flour may be produced by mechanical means alone. A much greater decrease, partly permanent in character, can be made by severe treatment.

17) The absorptive capacity varies with the protein content of flours of the same grade. This relation is not so marked between different flour ure; 5 grades.

18) The absorptive capacity of flour, starch, hydrolised starch, and bread is greatest at zero, decreasing with increasing temperature; 50 degrees makes a difference in absorption of from 16 to 24 per cent with these substances.

19) Sprouted wheat flour has on the average a 2 per cent lower absorption than that from the same wheat in the natural state.

20) Both normal and sprouted wheat flour increase in absorptive capacity during storage; in some instances as much as 3 or 4 per cent. The average increase of 34 samples in 8 months was 1.22 per cent.

21) The proportion of water in gluten is slightly higher under conditions which give it the greatest freedom during its formation, *i. e.*, with higher temperatures, or with more water at its disposal.

22) Approximately 180 per cent of water is absorbed by gluten and once it is formed it retains practically a constant amount of water at all temperatures below its decomposing point.

23) Tho absorption of a starch gluten mixture is less than the sum of the absorption of the two taken separately.

24) By hydrolysis starch has its capacity for water doubled. By dextrinisation it is markedly decreased.

25) By baking or by decomposition gluten has its capacity for water decreased. Baked gluten does not vary in water capacity with change in temperature.

26) The maximum staleness of bread occurs when the ratio of water present in the bread to the capacity of the starch is least, or the fresher the bread the more nearly satisfied with water are its starch particles and with a given moisture content this satisfaction would vary with the temperature changes inversely as the absorptive capacity of either starch, hydrolysed starch, or bread.

27) The capacity for moisture of the inner portion of the bread indicates that practically all of the starch is hydrolysed during the baking process. That of the crust is less, indicating some dextrinisation.

28) The higher the starch content of a flour the more water would it require in proportion to its capacity to produce a loaf of a given apparent freshness.

1160 — **The Decortication of Peanuts.** — I. MATHON, E., Rapport tendant au décortilage des arachides du Sénégal (Report on the Decortication of Peanuts from Senegal), in the *Institut Colonial de Marseille, Section des Matières Grasses, Bulletin*, No. 2, pp. 3-13. Marseilles, 1917. — II. Peanut Decorticating Machines, *Ibid.*, *Bulletin* No. 4. Marseilles, 1918.

I. — The annual peanut crop of French Senegambia alone varies from 250 000 to 300 000 metric tons with an average volume of 106 cu. ft. per metric ton. More than  $\frac{2}{3}$  of this amount has to be removed quickly, before the first rains, as the existing stores cannot hold more than 100 000 metric tons, though they have been considerably enlarged the last 2 or 3 years.

In normal times the ordinary shipping lines did not suffice for this trade and recourse was had to Scandinavian boats lying idle at home at the period when extra tonnage was required for Senegal. Now, this no longer takes place and the question of shipping peanuts from French West Africa is of prime importance. What is required is that the yield of the ship placed at the disposal of the importers should be increased by decorticating the peanuts.

One thousand lb. of peanuts in their shells, as they usually are exported, include 700 lb. of seed, 260 to 270 lb. of shells and 30 to 40 lb. of earth, straw, sand, etc.

The specific weight is 652 to 706 lb. per 100 cu. ft. of peanuts in their shells and 1266 to 1287 lb. per 100 cu. ft. of decorticated peanuts. Again, on a ship 500 lb. of loose undecorticated peanuts take the same space as 800 lb. of decorticated nuts in sacks. Thus the carriage of 100 000 tons of decorticated nuts would give an economy of 56 % over 100 000 tons of undecorticated nuts. It is evident, therefore, that the tonnage of ships required for transporting the decorticated nuts from Senegal would be only one half that required for transporting the same quantity of nuts.

How can this result be arrived at? In countries that usually export decorticated nuts, the natives decorticate them (India, East Coast of Africa). In Senegal this is not the case and machinery would have to be used; but machinery breaks many nuts, which does not matter if the nuts are used at once, but which is of great importance if the operation is carried out for the purpose of transport. The question of power or hand (for home use) machines is being studied at the Colonial Institute at Marseilles.

Up to the present the rise in freights had damaged the producers by lowering the selling price. Now the increased freights will be profitable to them when decorticated peanuts are shipped, for they will allow of an increased buying price. The author thinks there is no fear of painting the benefits of this in too bright colours to the natives in order to stimulate them in the work of decortication. The expenses will be largely covered by all sorts of advantages, such as the profit, which will be considerable for the natives, who will be better paid; the Colony, whose prosperity will be increased by the extension of its crops and the greater prosperity of its inhabitants; the railways, which will have more traffic; the commercial men whose stocks will be better maintained by the same number of steamships; and even the consumers, on account of the decreased cost price. In addition, the warehouses, with the same capacity will be able to store more,

so that the exporting season can be lengthened; the seeds sold will be freed from the always increasing amounts of impurities; the buying season, obligatorily reduced to 5 or 10 weeks can be lengthened slightly; the ships will not be idle so long in the ports as a sacked cargo can be loaded more quickly than a loose one.

II. — The Fats Section of the Colonial Institute at Marseilles gives a description of the modern machinery known to it for decorticating peanuts.

There are 2 types of decorticators: one decorticating between a grooved cylinder and a grooved scraper, the grooves varying in form and direction according to the type of machine (those of ARMAND & DÉOUNE, Marseilles, and some American machines); and one with a threshing machine (GAUDART machine), a type employed in India.

Messrs ARMAND & DÉOUNE, of Marseilles, make two types: — one gives a yield per hour of 1041 lb. of decorticated peanuts ready for sale, and 55 lb. of broken kernels, etc.; the other is on a bigger scale, and gives 3300 to 4400 lb. of decorticated peanuts. The large machine includes, as well as the usual machinery, a fan that removes the seed-shells, straws, stones, etc.

M. R. GAUDART, of Paris, makes peanut decorticators with threshing organs of which the type B3 gives the best results. A machine has been installed in the buildings of the Madras Presidency Agricultural Department, for demonstration to the natives. This machine — type B3 — can deal with from 2200 to 2640 lb. of undecorticated peanuts per hour, working continuously according to the degree of dampness of the grain. Eight H. P. are required to run the machine at 180 revolutions a minute. The seeds broken vary from 5 to 15 % according to the degree of humidity. This machine may be installed in groups of 2 or 4. A group of 2 decorticators with a double-fan winnowing machine can treat 25 metric tons of undecorticated peanuts giving 18 tons (75 %) of decorticated seeds; 2 H. P. and 11 workmen will be necessary. Two groups united form a plant that can produce about 77 000 lb. of decorticated peanuts per day; 50 H. P. and 20 workmen would be required. In India Messrs BEST & Co., of Pondicherry, make the GAUDART machines.

Messrs ROSE, DOWNS & THOMPSON, Ltd., of Hull, make cylinder decorticators that are made rather for oil-works where peanuts are pressed. The machines are in 4 sizes: — No. 200, with a sieve, treating 1 metric ton of peanuts per hour; No. 201, idem, treating  $\frac{1}{2}$  that amount per hour; No. 202, idem, treating  $\frac{1}{4}$  that amount per hour; and No. 203, worked by hand or power, treating 165 lb. per hour. Messrs BAERLEIN & SONS, of Manchester, offer the same machines as the preceding ones. The HUNTLEY MANUFACTURING Co., of Silver Creek, N. Y., U. S. A., makes the "Monitor Houston" of the thresher type with a capacity of about 1100 lb. per hour.

The APPOMATTOX IRON WORKS & SUPPLY Co., Petersburg, Va., U. S. A., make several machines that deal with from 6600 to 16 500 lb. in 10 hours; the machines decorticate the nuts and remove the shells by a current of air. This Company makes 2 small cylinder machines: — "Appomattox", No. 0, of 1100 lb. capacity in 10 hours, and No. 3, of 3300 to 3850

lb. capacity per 10-hour day. The last-mentioned machine sorts the separated shells into 3 grades.

The CARDELL MACHINE Co., of Richmond, Va, U. S. A., makes cylinder decorticators and separators of various sizes, driven by hand (10 to 15 sacks per hour) or power (150 sacks per day).

The JOHNSON & FIELD MANUFACTURING Co., of Racine, Wis., U. S. A., makes power-driven machines of various sizes for separating and sorting the peanuts as well as sacking them by means of an elevator.

**1161 - Vinegar from Waste Fruits.**—CRUESS, W. V., in the *University of California College of Agriculture, Agricultural Experiment Station, Bulletin No. 287*, pp. 169-184 + 11 Figs. Berkeley, California, October, 1917.

Fruit unsuitable for sale fresh, for drying or for canning, may often be used for the manufacture of vinegar or acetic acid, from which is obtained acetone, used in the manufacture of high explosives. One ton of apples, grapes, or most deciduous fruits, will yield from 140 to 175 gallons of juice suitable for the making of vinegar; oranges yield about 100 to 125 gallons. Apples give about 75 lb. of acetic acid per ton, grapes about 150 lb., and oranges about 50 lb. In California, at 15 cents per gallon, vinegar from one ton of apples or grapes is worth approximately \$ 23, and from a ton of oranges about \$ 15. Estimating the value of acetone at \$ 2 per gallon, the acetone from one ton of apples is worth about \$ 7, that from 1 ton of grapes about \$ 13, and from one ton of oranges \$ 4.50.

The profits from the manufacture of vinegar are moderate. There is a demand for acetone, but its manufacture requires a special installation and should only be undertaken on a large scale and where a large supply of cheap fruit is available.

The author studies the principles of vinegar production rather than equipments on a large scale, but if the principles examined are well understood they may easily be applied to manufacture both on a large or a small scale. All the common fruits, with the exception of lemons, and inferior quality dried fruits may be used for the manufacture of table vinegar so long as they are sound and clean. For making acetone the condition of the fruit is of no importance. Cannery waste (peel and cores) give satisfactory vinegar if sufficiently clean, otherwise they may be used for the manufacture of acetic acid or acetone.

The crushing and pressing of the fruit, fermentation, clarification, bottling and diseases of vinegar are described successively. Most fruits can be pressed most satisfactorily if previously crushed and fermented. Vinegar making depends on two fermentations; in the first the sugar is turned to alcohol and carbonic acid by yeast; in the second the alcohol is turned into acetic acid by acetic bacteria. To obtain good results the two fermentations must be made separately. Pure yeast (the preparation of which is described) and a small amount of sulphurous acid must be used to insure good alcoholic fermentation and to eliminate lactic bacteria.

The fermented juice should be kept for two or three weeks to free it from the yeast and other solid particles and should be decanted before acid fermentation begins. To the racked juice should be added  $\frac{1}{4}$  its.

volume of fresh vinegar to start the acid fermentation and prevent diseases. The fermented acid juice may then be made into vinegar by the slow process in barrels or by the rapid process in generators (fixed or rotating) which are fully described and illustrated. The vinegar should then be aged (1 year for the best quality). During this process it may clarify sufficiently to be bottled for sale, but usually filtration or the addition of some clarifying substance is necessary.

**1162 - The Scott Process and Plant for Drying Potatoes.** — See No. 1152 of this Review.

**1163 - Straw Hats and Braids in South America.** — *The South American Journal*, Vol. LXXXIV, Nos. 18, 19, 20, pp. 281-282, 299, 315-316. London, May 4, 11, 18, 1918.

**ARGENTINA.** — Straw hats are worn generally in Argentina from October to May. According to Mr. ROBERTSON, the U. S. Consul General at Buenos Ayres the wholesale prices in 1914-15, according to the shape and quality, were 30 s to 78 s per dozen for "canotiers". 5 s. 6 d. to 62 s. per dozen for round crowned hats for men, 11 s. 6 d. to 24 s. per dozen for round crowned and sailor hats for children, 30 s to 84 s. per dozen for black rustic straw hats. During these years the retail price depended on the stock in the market, and varied from 4 s. 6 d. to 10 s. 6 d. each. In September, 1917, the prices exceeded those of 1914-15 by £ 1 per dozen.

Before the war the proportion of imported hats was about 200 % of the national production. Argentina produces from 24 000 to 31 000 dozen straw hats annually. The machinery used is of foreign origin; the presses come from France and Italy and the sewing machines from Germany and North America.

The importation of straw braid rose from 55 118 lb. valued at £ 4 500 in 1915 to 81 095 lb. valued at £ 6 150 in 1916. Previously these imports came from Germany, France, Italy, Switzerland and England, but now they come from England and Switzerland. No special fibre suitable to the manufacture of straw hats is known in Argentina, but it is probable that no special study has been devoted to this subject.

**BRAZIL.** — Straw hats are worn practically throughout the whole year though felt hats are also worn during the winter months. Stiff straw hats are mostly worn in the towns; labourers working in the open wear very cheap soft straw hats. Panama hats are in very small demand. Hats for women are usually made of horsehair or vegetable crin, which are believed to come from China or Japan.

Practically all the imported straw hats come from Italy. The imports were estimated at £ 15 800 in 1913, £ 5 200 in 1914, £ 2 300 in 1915, £ 950 in 1916. In 1915 there were 269 hat factories in the State of San Paulo, only 6 of which are important. These factories also make felt hats. In 1915 1 012 594 hats valued at £ 400 000 were produced, in 1916 1 200 000. The only machines used in these factories are sewing machines, mostly of German make.

The straw braid comes from Switzerland ( $\frac{3}{4}$ ) and Italy ( $\frac{1}{4}$ ). In 1913 the imports were 53 533 lb. valued at £ 12 000; in 1914 they decreased,

rose slightly in 1915, and in 1916 were 48 847 lb. valued at £ 14 000. Nearly all the braids are sold in lengths of 60 yds. Very little dyed braid is sold. All these quantities are imported through the port of Santos ; those imported through Rio de Janeiro are not known. The native production is limited to coarse braids used for making labourers' hats. A few native hats are woven from fibre made from plants growing in the country.

URUGUAY. — Straw hats are largely worn in the towns by the upper and middle classes, but much less so by the working classes. The number sold annually is estimated at 8 000 dozen for men, 3 000 dozen for women, and 10 000 dozen for children; 80 % of these hats is manufactured locally, the remainder are imported. In 1915 fine straw hats to the value of £ 1 060 were imported from Great Britain (460 doz.), Italy (128 doz.), France (11 doz.); cheaper qualities come from Italy (1 034 doz.), Great Britain (961 doz.), France (21 doz.), Argéntina (20 doz.), Spain (12 doz.); their value is estimated at £ 2 300. The straw-hat industry has made great strides in Uruguay during the last two years, largely owing to the import duties imposed in 1915. The present annual output is estimated at 16 000 to 20 000.

All the straw braid used by the factories is imported, the quantity being estimated at 120 000 to 150 000 pieces of 50 metres of an approximate value of £ 4 000. The braids come from Japan and Italy; in both cases they are imported through England or France, where they are bleached. Bleached straw is most largely in demand for men's hats, Tagal straw 4 to 5 mm. wide is preferred for women's hats. All transactions are done at 6 months' credit, and it is clear that exporters demanding cash would be at a great disadvantage against competitors giving credit.

PERU. — There is but a small market for braid in Peru as 50 % of the straw hats are made in the country. It is very difficult to obtain statistics on this industry. The straw hats manufactured annually are estimated at 80 000 dozen, 25 % of which are servants' or bathing hats. In 1915 75 % of the importations came from Italy, 15 % from Great Britain, and the rest from France, Chile and the United States. No statistics are available for 1916. The straw-hat season along the coast lasts 7 months, but inland straw hats are worn throughout the year. The Indian population wear servants' or bathing hats, or cheap Panama hats made in Ecuador or the north of Peru. There are four straw hat factories in Peru; the presses used are of Italian make, the sewing machines English or German.

VENEZUELA. — Cheap hats are usually made by hand and sold to the working classes. Nearly all the straw hats are made locally, the import duties being prohibitive. Statistics on the importation of straw hats are not available. The centre of the native production is at Valencia, where there are three factories working with a total annual output probably below 100 000 hats. The machinery used is Italian and American. Near Coro cheap hat making is a home industry; the women plait palm straw and make of it hats which sell at 4 s a dozen. There are no statistics showing the amount of raw material imported. Nearly all imported braid is bleached, preference being given to that from Europe rather than that from the United States.

COLOMBIA. — Straw hats are worn all the year round. Panama hats are made from native grasses in the interior, but the better quality hats are more expensive than the imported ones which have increased in popularity of recent years. Two small hat factories have been started at Barranquilla and Cartagena. The Barranquilla factory has 15 sewing machines worked by electric power and four presses, and has an output of 25 dozen hats a day. The prices vary according to the quality from £ 2 to £ 5 per dozen. Retail prices are from 4s upwards. All the materials used in these factories are imported from the United States, though the braid originally comes from Italy, China, and particularly Japan. The annual imports amount to 16 000 pieces of 60 yds. Both soft and stiff straw hats are made with various kinds of braid and compare favourably with the imported hats.

INDUSTRIES  
DEPENDENT  
ON ANIMAL  
PRODUCTS

1164 — **The Condensed Milk Industry in Japan.** — Abstract from the *Jiji Shimpoo*, April 23, 1918 in the *Department of Trade and Commerce, Canada, Commercial Intelligence Branch, Weekly Bulletin*, Vol. XVIII, No. 750, pp. 893-894. Ottawa, June 10, 1918.

The use of condensed milk in Japan probably dates from 1880. The condensed milk imported into Japan at one time amounted to 1 200 000 dozen cases with a value of 4 500 000 *yen* (£460 323). Since then a condensed milk industry has developed in Japan. The produce, of inferior quality at the beginning, has improved considerably and can now compete with foreign condensed milks and is being exported in large quantities.

The centre of this industry is at Mishima, in the prefecture of Shizuoka. There are 2 776 dairy cows, 1 000 of which supply approximately 40 *koku* (1600 gallons) of milk daily. To prepare one case of condensed milk (4 dozen tins per case) 33 *sho* (52.14 gallons) of raw milk are necessary. The factory, therefore, is able to produce about 3 600 cases a month.

The conditions in Japan are excellent for the production of condensed milk, the quality of which depends on the climate, the drinking water and the fodder. The local farmers undertake cattle breeding as a secondary occupation, devoting much care to it.

A table giving the production, importation and exportation of condensed milk in 1913, 1914, 1915 and 1916, shows that local production has increased greatly and that the importation has dropped considerably though the exportation has continued to increase. At the present time Japanese brands of condensed milk are quoted at \$ 9 to \$ 9.60 per case of 4 dozen tins, whereas the imported brands sell at \$ 10.87 to \$ 11.25 per case. An analysis made by the Hygienic Laboratory of Japan showed the quality of Japanese condensed milk to be superior to that of foreign brands.

1165 — **The Reducing Ferments of Milk.** — PERRIAZ, J., in the *Archives des Sciences Physiques et Naturelles*, Year CXXIII, Period 4, Vol. 46, pp. 101-102. Geneva, 1918.

In order to study the reducing ferments of milk the author took samples direct from the byre and treated them immediately so as to avoid the subsequent action of reducing ferments. The method employed was as follows:— 10 cc. of milk diluted with sodium nitrate and acetic aldehyde are left for one hour in an incubator at 60°; the serum is filtered, lead sub-

acetate added, and again filtered. It then contains reducing ferments, estimated as  $N_2O_3$  with a titrated solution of sulphanilic acid and acetic naphthylamine.

RESULTS. — 1) There is no connection between the very minute quantity of reducing ferments and the natural components of milk — water, casein, sugar, albumin, etc.

2) The quantity of these reducing ferments depends on the following factors:— *a*) the animal species; the milk of mares and asses is richer than that of cows, goats, or sheep; *b*) the system of feeding and the food; mountain hay gives milk very rich in ferments, beet and cake very poor milk; *c*) the age of the animal; young animals give very poor milk, old ones a much richer milk. At the beginning of milking the milk is almost devoid of reducing ferments (0.08 mgm. per 10 cc.) whereas this content increases very greatly towards the end.

3) Boiling causes these ferments to disappear *completely*; they are destroyed by temperatures between  $75^{\circ}$  and  $80^{\circ}$  C. It results that sterilisation removes from milk a very important element of its digestibility.

#### 1166 — The Churning of Sweet Cream and Acid Cream: Investigations in Sweden (1).

— HESSELBERG, O., in the *Nordisk Mejeri-Tidning*, Year XXXIII, No. 13, pp. 267 269. Stockholm, June, 1918.

The author seeks to determine whether it is more advantageous to churn sweet cream or acid cream. Of late years the production of butter has assumed more and more the character of an industry the technique of which demands the most modern ingredients and methods, such as pasteurisation, the use of pure lactic ferments, etc., and all improvements in technique have always been concerned with the churning of acid cream. Moreover, should there be any defect in flavour, the consumers, always very exacting in this respect, never fail to impeach the churning of sweet cream should the dairy adopt this method.

To what extent is the preference for acid cream justified? The two principal factors in the production of butter are yield and quality. The maximum average yield which may be obtained from 100 lb. of milk (with 3.5 % of fat) by churning acid cream may be calculated by means of the following data:— cream 12 lb., skim milk 86 lb., buttermilk 8 lb.; fat content of skim milk 0.08 %; fat content of buttermilk 0.50 %, fat content of butter 81 %, moisture content of butter 15 %.

It is seen that the fat content of skim milk is  $\frac{0.08 \times 86}{100} = 0.069$  lb., that of buttermilk  $\frac{0.50 \times 8}{100} = 0.040$  lb., or a total of  $0.069 + 0.040 = 0.109$  lb. which must be subtracted from the fat content of the 100 lb. of milk used ( $3.5 - 0.109 = 3.391$  lb.). The butter yield from these 100 lb. of milk obtained by churning acid cream is, therefore,  $\frac{3.391 \times 150}{81} = 4.186$  lb.

When sweet cream is churned the calculation is somewhat different.

(1) See also R. July, 1918, No. 819. (Ed.)

The amount of cream (12 lb.) and skim milk (86 lb.) remain the same, but as the butter-milk is very fat in this case it has to be skimmed again and its fat content is decreased (0.3 %). The butter from acid cream seems slightly richer in albuminoids and, consequently, the fat content of butter from sweet cream may be slightly higher. The moisture content may be adjusted in both cases. The average yield of 100 lb. of milk (with 3.5 % of fat) obtained by churning sweet cream may, therefore, be calculated by the following data:—cream 12 lb., skim milk 86 lb., buttermilk 7.3 lb., buttermilk obtained from the "buttermilk cream" (kärnnyölkefter kärnnyölksgrädden, second churning) 0.7 lb., fat content of skim milk 0.08 %, fat content of buttermilk 0.30 %, fat content of buttermilk obtained from the "buttermilk cream" 1.0 %, fat content of butter 81.3 %, moisture content of butter 15.0 %.

There are 0.069 lb. of fat in the skim milk, 0.022 lb. in the buttermilk and 0.007 lb. in the buttermilk from the "buttermilk cream", or a total of 0.098 to be deducted from the fat content of the 100 lb. of milk used (3.5 — 0.098 = 3.402 lb.): The yield in butter of 100 lb. of milk obtained by churning sweet cream is, therefore,  $\frac{3.402 \times 100}{82.3} = 4.184$  lb.

*The yield is, therefore, almost identical in both cases.*

The method usually adopted in churning sweet cream is as follows:—the butter-milk is skimmed and the cream obtained added to the other cream obtained during the day. This is a great mistake from the point of view of both yield and quality. If, on the other hand, the "buttermilk cream" is churned a second time one week later, when it is "ripe" the yield is excellent.

The advantages of churning sweet cream are:—

- 1) it is unnecessary to acidify the cream;
- 2) defects in quality due to the acidification of the cream are avoided;
- 3) butter made from sweet cream keeps much better than that made from acid cream; the author showed that, in the first case, butter was perfectly fit for consumption even after two or three months, whereas, in the second case, it deteriorated after fifteen days; these superior keeping properties are seen especially during the summer and autumn months.

**1167 — The Preparation of Home-made Rennet.**—TODD, A., and CORNISH, E. C. V., in *The Journal of the Board of Agriculture*, Vol. XXIV, No. 3, pp. 307-312 + 3 Tables. London, June, 1917.

The method described is as follows:—to 1 gallon of brine filtered through paper or muslin and 2 oz. of boric acid are added 15 vells freshly split and washed, which are left to soak for one week in a cool place, the mixture being stirred daily. When the mucous membranes are soft they are scraped off and returned to the original extract (first steep), which is kept till it attains a suitable strength. It is then filtered through cotton-wool and the rennet bottled and kept in a cool, dark place. The scraped vells are placed in half the original quantity of fresh brine (second steep) and the extract, though much weaker than the first, is treated in the same manner.

The strength of extracts obtained by this method compares favourably with that of commercial rennet and they retain their coagulating properties for several months, their strength often increasing with keeping. Over 1 300 gallons of milk were made into entirely satisfactory cheeses by the use of these extracts.

1168 - **The Preservation of Meat: Researches on the Presence of Living Elements in Normal Muscular Tissue (Parasitism and Microbiosis).** — GALIPE, V., in the *Comptes Rendus de l'Académie des Sciences*, Vol. CLXVII, No. 4, pp. 178-180. Paris, 1918.

Many workers (BÉCHAMP, NENKI and GIACOSA, BILLROTH and FIEGEL, BURDON-SANDERSON, GAUTIER and ETARD) have demonstrated the presence of living elements in muscular tissue and the autonomous persistence of intracellular life. The author, having carried out further work on the question, gives his conclusions which are of interest from the standpoint of food hygiene.

Pieces of meat of even the best appearance are colonised not only on their surface but internally, as much on account of normal and accidental parasitism as on account of the activity of microbiosis. The progress of microbiosis is favoured by attrition, whether experimental or accidental, of the muscle tissue, thus decreasing its capacity for preservation. Meat juice extracted under heavy pressure is rich in microorganisms and micro-enzymes (*microbiose*). The colonisation of butcher's meat, which can take place 2 to 3 hours after slaughtering, is so rapid that it is impossible to accept the common theory according to which microbial colonisation takes place solely from exterior to interior through the parasites deposited on the meat during handling. Other causes, as yet unknown, probably play a part (*e. g.*, attrition during dressing which might favour the development of microbiosis close to the muscular tissue). Perhaps the method of slaughtering may have an influence. Fragments of muscular tissue of a healthy animal were removed under strictly aseptic conditions; 3 days after inoculation, the cultural centres were found to be colonised and others gave positive results after 48 hours. These muscular tissues only decomposed after 22 days, but gave off no odours of putrefaction. In consequence handling meat under conditions of irreproachable cleanliness is most desirable and would greatly diminish the proportions of poisoning due to meat. In his cultures the author found mitochondrial forms resembling the condriocontes described by GUILLERMOND in the epidermis of the tulip and by MULON in a cell of the supra-renal capsule of the guinea-pig, as well as spores and mycelial tubes. The author attempted to ascertain if chilled meat was less contaminated or not than fresh meat; a fine-looking piece of chilled meat of excellent taste was found to be colonised just as much as that coming from the slaughter-house, and cultures gave positive results after 24 hours. These results were again due to normal and accidental parasitism and microbiosis. In consequence refrigeration does not destroy those microorganisms deposited on the surface of the meat during handling any more than it does those the meat usually contains; it can slow down or suspend the activity of the different microbical elements in proportion to the lowering of the temperature, but the activity recommen-

ces as soon as the cold ceases. From the standpoint of the preservation of food stuffs the action of heat may be compared to that of cold.

**1169 - Food Preparations Made with Blood and Meat Mixed with Yeast.** — GANDUCHEAU A., in the *Comptes Rendus de l'Académie des Sciences*, Vol. CLXVI, No. 25, pp. 1058-1059. Paris, 1918.

Under present conditions it would be very advantageous to use the blood and intestinal organs, generally wasted by the slaughter-houses, to a greater extent for human consumption than has hitherto been the case. The author proposes a new food prepared from this waste as follows: — the blood of pigs, oxen and horses is taken under special aseptic conditions from the slaughter house as soon as possible after the animals have been bled and successively heated for coagulation of the albumens and disinfection; it is then crushed and fermented with a pure culture of beer yeast (fermentation under slightly acid conditions in the presence of a small quantity of starch sugar obtained from rice, potato, pea-shells etc., by warm diluted hydrochloric acid). After a few hours at a maximum temperature of 20 to 25°C the pasty mass ferments and a microscopical examination shows the presence of pure yeast cultures.

The paste thus obtained, strongly modified by the action of the yeast, is not so compact as that of black-pudding or other similar products, and has numerous small holes caused by the gas formed during fermentation. The porous product is thus more easily acted upon by the digestive juices. Visceral tissues when finely crushed previously may be prepared in the same manner as blood.

With respect to the application of bread fermentation to blood and meat, a subject already treated in previous papers (SCHEURER-KESTNER, *C. R. Acad. des Sc.*, 1880, p. 369 and CHARDIN, *ibid.*, 1890, p. 670), the author points out that the materials used (bread made with mixed flours, leaven, hashed meat and blood) were bacteriologically impure and, as they were not heated before fermenting the leaven had combined with the yeasts and bacteria, a disadvantage incurred also in the oriental process in which mixed meat and bean pastes are used.

For this reason the technique used in fermenting albuminoids should be rigorous and, above all, pure cultures should be used. "Risen" blood paste is excellent for making sausages and pastry, and gives products with a very good flavour. Blood and flour biscuit is a complete food of small bulk and the author believes that the use of the blood from slaughter-houses may prove very interesting from an economic point of view.

**1170 - The Preservation and Efficient Ripening of Silage in Warm Countries: the Use of Hydrochloric Acid or other Acid Mineral Substances and Special Substances** — GIGLIOLI, J. (Professor of Agricultural Chemistry, University of Pisa), paper read before the International Association for Tropical Agriculture, Third International Congress of Tropical Agriculture held at the Imperial Institute, June 23 to 30, 1914. Reprinted from the *Transactions of the Congress*, Vol. II, 29 pp. + Bibliography of 30 Publications. London, John Bale, Sons and Danielsson, Ltd., 1917.

In warm, dry countries ensilage is more useful even than in mild, damp climates, 1) because of the long summer without green fodder;

2) because of the lower value of hay resulting from its more rapid drying, and 3) the waste material from bushes and wild plants which dries badly and needs a special fermentation process before cattle will accept it. Preservation in silos is much more difficult in hot than in temperate climates. So that the material in the silo shall change little and slowly the use of salt (denatured for cattle) has been advised but little used. Several methods have also been tested: — 1) Steaming the ensilage; 2) heating, cooking, inoculation with lactic ferments; 3) addition of molasses or sugar; 4) treatment with special antiseptics, such as carbon bisulphide, etc., 5) treatment with acids, especially mineral ones, or with mineral acid substances.

1) STEAMING. — Tends to keep the acidity of the ensilage low and makes it easily apt to spoil when the silo is open; it is also expensive and not always easy to apply.

2) INOCULATION WITH LACTIC FERMENTS. — The bacteria consume very actively a large part of the organic matter of the silage so that, from this point of view it is best to eliminate them completely. On the other hand they assist in the production of the total acidity of the fodder in the silage which, being more useful the more fixed it is (as, e. g., when it is produced by lactic acid), has a protective action against the most harmful anaerobic bacteria and especially against all those which tend to develop rapidly before the silo is completely filled and when it is opened. It is for this reason that a predominance of lactic ferments is encouraged by adding cultures of them to green fodder in filling the silo. The pulp of sugar beet is well suited to this treatment and has been used in France where a product "lacto-pulpe" for inoculating beet pulp and other fodder for ensiling has been put on the market, in Austria, where pure cultures of acid-producing bacteria for this inoculation are sold under the name of "Vindobona-Pulpe", in Connecticut, U. S. A., and in Italy as a result of the work of Prof. GORINI (1). In warm countries, however, the use and transport of bacterial cultures over long distances are rather unsafe, the fermentations of the fodder are more complex and heterogenous, so that the one which should predominate is not sure to do so, etc. For all these reasons it seems more rational, to assure the protective action of acids, to add the acids to the fodder in the most unchangeable and efficient form, that of mineral acids, instead of waiting till the bacteria, as a result of their complex actions, evolve an acid which ferments more easily.

3) ADDITION OF SUGAR. — The addition of molasses was tested by Dr. SAMARANI at the cheese-making Station of Lodi, as a complement to inoculation with lactic ferments on a basis that the presence of sugar favours lactic fermentation at the expense of butyric fermentation. The author notes that: 1) the addition of molasses, from this point of view, should be necessary for leguminous fodders poor in sugar but rich in protein; 2) in warm countries it is best to use molasses in much larger quantities to take advantage of their antiseptic properties and high food value in association, not

(1) See R. 1915, Nos. 541, 923, 1145; R. 1916, Nos. 109, 232; R. 1918, Nos. 473, 918. (Ed.)

with the inoculation of lactic ferments, but with hydrochloric acid, in quantities corresponding to the acidity of a good acid silage, for example, 2 %.

4) ANTISEPTIC TREATMENT. — The use of carbon bisulphide for preserving silage, proposed in 1887 by Dr. GRETE (Zurich, Switzerland) and successfully tested with clover the same year (1 cc. per litre of capacity of the silo), was later tested with good results in Haute-Garonne, France (carbon bisulphide in Jemain capsules, 5 lb. per metric ton of crimson clover), in Sweden, and in Russia (red clover, cabbages, carrots). Carbon bisulphide inhibits to a marked degree the development of free organic acids in the silage. It would be well to test it or carbon tetrachloride in warm countries. In fodder containing cyanogenetic substances (sorghum, for example) the vapour of carbon sulphide or tetrachloride, by giving rise to enzymic actions, might cause the liberation of hydrocyanic acid; the question, therefore, calls for further study.

Dr. GRETE also experimented with sulphur dioxide; these tests should be repeated in warm countries. This gas has a triple action:— a) it inhibits oxidation; b) it stops bacterial action and the development of moulds, and probably lessens all enzyme action; c) by oxidising it forms sulphuric acid, which would keep the silage unchanged till it is taken to the stables.

5) TREATMENT WITH ACID SUBSTANCES. — The author proposed the use of acid substances, especially mineral acids, many years ago at the High School of Agriculture at Portici, Naples. In an experiment, he added to maize silage, besides common salt, 2 % of an organic acid substance (citric acid, tartaric acid, or cream of tartar). In another experiment he watered the fodder as it was being put into the silo with 5 % hydrochloric acid or commercial hydrochloric acid diluted with 10 volumes of water (this method could also be used for preserving mulberry leaves for silkworms). Before giving fodder preserved with hydrochloric acid to stock it must be moistened with a solution of sodium carbonate, which neutralises the acidity and seasons the fodder with sodium chloride. The action of hydrochloric acid could be combined with that of sulphur dioxide by means of sodium bisulphate.

At Perugia, Italy, Prof. SANI successfully used, in 1912, monocalcium phosphate (300 gm. per quintal of fodder) by spreading it over clover as a big iron silo was being filled.

In 1885 WEISKER showed that a limited quantity of mineral acids in the fodder is not injurious to stock. On the other hand, it is easy to remove excessive acidity from fodder when it is fed by sprinkling with sodium carbonate or powdered lime. This is good for milk production and small quantities of calcium chloride help the growth of animals.

The author believes hydrochloric acid to be preferable to sulphuric acid; the first is naturally in the gastric juice and, by neutralisation gives salts preferable to sulphates. Sodium chloride also has a specific action, not yet well explained, which prevents the injurious action of certain toxins which might form in silage, at least in that of sugar beet pulp (ARLOING, 1883).

LEGISLATIVE  
AND  
ADMINISTRATIVE  
MEASURES

By the order No. 37 of 1918, given out on March 28, 1918, the coconut butterfly (*Brassolis sophorae*) is declared injurious to agriculture in the Colony of Trinidad and Tobago.

### DISEASES DUE TO FUNGI, BACTERIA AND OTHER LOWER PLANTS.

- 1172 - Myxomycetes and Fungi of the Province of Verona, Italy. — SACCARDO, P. A., in *Madonna Verona*, Year 1918, pp. 1-24 of the Reprint. Verona, 1918.

GENERAL

List of 3 Myxomycetes and 173 fungi identified by the author from material collected by Prof. C. MASSALONGO at various periods in the province of Verona, and to which were added some forms from the herbarium of the late A. MASSALONGO.

Five species and one variety of fungus are described as new to science.

Amongst the fungi quoted, many were observed on cultivated or useful plants.

- 1173 - Fungi from Singapore, Malacca and Campania (Italy). — SACCARDO, P. A., in the *Bollettino dell'Orto botanico della R. Università di Napoli*, Vol. IV, pp. 39-73. Naples, 1918.

I. — In 1917, Prof. C. F. BAKER collected a large number of fungi in the Botanical Garden of Singapore and sent them to the author for identification. The author found the material contained 90 species and varieties; of this number, 2 genera, 57 species and 8 varieties are given as new to science.

The following are worthy of special mention: —

- 1) *Aecidium Cassiae* Bresad., on leaves of *Cassia Tora*;
  - 2) *Meliola Mangiferae* Earle, on living leaves of *Mangifera indica*;
  - 3) *M. æthiops* Sacc. n. sp., on living leaves of *Cassia Fistula*;
  - 4) *M. mangostana* Sacc. n. sp., on leaves of *Garcinia Mangostana*;
  - 5) *Xylaria (Xyloglossa) tuberiformis* Berk., on *Hevea brasiliensis*;
- a doubtful species as the specimens examined were sterile;

6) *Xyl. (Xylogl.) obovata* Berk., at the base of trunks of *H. brasiliensis* ;

7) *Xyl. (Xylogl.) scopiformis* Mont. var. *heveana* Sacc. n. var., on trunks of *H. brasiliensis*.

II. — A list is given of 21 species and varieties new to science collected in the province of Avellino (Italy), save 2 from the province of Caserta (Nola) and Salerno (Scafati).

Nearly all the forms from the province of Avellino and from Nola were found on dead wood or branches of hazel (*Corylus Avellana*).

The author gives the name of *Cladosporium densum* n. sp. to the fungus found at Scafati on dead or dying stems of *Ricinus communis* and possibly injurious to the host-plant from the start.

DISEASES  
OF VARIOUS  
CROPS

1176 — *Odontia Sacchari* n. sp. and *O. saccharicola* n. sp., Basidiomycetes Living on Sugar Cane, in Porto-Rico, Antilles. — BURT, E. A., in the *Annals of the Missouri Botanical Garden*, Vol. IV, No. 3, pp. 233-236 + 2 Figs. St. Louis, 1917.

Description of the following two new species of Hydnaceae collected in Porto Rico by Mr. J. A. STEVENSON :—

1) *Odontia Sacchari* Burt n. sp., on the dead basal part of leaf sheaths of the sugar cane and on remains of the same plant, at Río Piedras; other specimens had been collected previously at Santiago de las Vegas (Cuba).

2) *O. saccharicola* Burt n. sp., on living stems of *Saccharum officinarum* and also of *Paspalum*, at Río Piedras and Canovanas.

1177 — *Phyllosticta Rabiei*, a Deuteromycete the Specific Agent of "Rabbia" or Anthracnosis of the Chick Pea in Italy. — TROTTER, A., in the *Rivista di Patologia vegetale*, Year IX, No. 17, pp. 105-111; Pavia, 1918.

Towards the end of the spring of 1918 a small crop of *Cicer arictinum* L., grown for demonstration purposes at the farm of the Royal School of Viticulture and wine-making at Avellino, was suddenly attacked, a little before flowering, by a disease which, in a few days, killed a large number of plants and weakened or partly withered others. The disease was especially marked on the stems, where the spots, which were more or less elongated and peripheral, were accompanied by a necrosis which developed in depth with great rapidity, even causing the tissues to lose their turgidity and the stem its stiffness, so that many plants broke easily at the point of infection. The petiole and rachis were also affected and the corresponding leaves turned yellow rapidly and withered.

A microscopic examination showed the disease to be of a fungoid nature, and it was identified as "rabbia" or anthracnosis of the chick pea, recently described by many authors. It seem identical with the "rabbia del cece", reported for the first time under this name by F. R. (1807). The disease was attributed by COMES (1891) to the parasitical action of *Ascochyta*

*Pisi Lib.*, and this theory was accepted by many later plant pathologists. The author's recent investigations made on living material and dried material from different sources, show it, however, to be caused by a species of the related genus *Phyllosticta*.

In giving a specific name to the *Phyllosticta* of the chick pea it is impossible to call it *Phyll. cicerina* Prill. and Delacr. (1893) as another micro-mycete is already known by that name. It was this fungus which, as a result of an imperfect microscopical examination of the pycnidial tissues, PASSERINI (1867) wrongly considered to be a nectroideae and described under the name of *Zythia Rabiei* whereas there is no doubt that it is the *Phyllosticta* studied by the author. It, therefore, appears necessary to re-establish PASSERINI's species but to place it in the genus *Phyllosticta*, using *Phyll. cicerina* Prill. and Delacr., the description of which was accompanied by no critical or synonymous comment, as a synonym. In this case, with our present knowledge of "rabbia" of the chick pea, and from a point of view of practical systematisation, the fungus causing this disease can only be classed as a *Phyllosticta*, which should be known under the specific name of *Phyll. Rabiei* (Pass.) Trotter.

## WEEDS AND PARASITIC FLOWERING PLANTS.

1178 - The Control of *Imperata arundinacea* (Gramineae) by means of *Leucaena glauca* (Leguminosae) in the Philippines. — See No. 1123 of this Review.

1179 - The Control of Weeds in Ricefields. — See No. 1106 of this Review.

## INJURIOUS INSECTS AND OTHER LOWER ANIMALS.

1180 - Notes on Some Aphides Collected in South Eastern Russia. — HAVILAND, M. D., in *The Entomologist's Monthly Magazine*, Vol. LIV (3rd Series, Vol. IV), No. 652 (45), pp. 200-202. London, September, 1918.

GENERAL

During the summer of 1917 the author collected several aphides on the steppes of south-eastern Russia. At the end of June and the beginning of July the collection was continued on the shore of the Black Sea, near Odessa; the author passed the rest of the summer at Reni, on the steppe near Galatz.

The species mentioned are:—

1) *Macrosiphum sonchi* Linn.; apterous specimens were taken on *Cichorium*, in August, at Bolgrad, Bessarabia, and on *Centaurea* in October at Odessa.

2) *Myzus cerasi* Fab.; not uncommon on wild cherry at Reni in July.

3) *Rhopalosiphum ribis* Linn.; at the end of June in a garden at Odessa shoots of a currant bush were found twisted by this species; one or two days later apterous specimens of *Rhop. lactucae* Kalt were seen.

4) *Aphis cardui* Linn. ( *A. myosotidis* Koch), on thistle at Odessa on June 30.

5) *A. laburni* Kalt; this species was very abundant at Odessa at the end of June and stunted and stunted young shoots of acacia, smearing them with honeydew: the winged form was just emerging at this time. The following week numerous newly-established colonies were found on *Melilotus officinalis* and alfalfa. Another aphid infesting a species of *Sambucus* in shrubberies and found also on *Chenopodium* near the sea, was found when examined comparatively, to be identical with *A. laburni*. This insect was preyed on by the larva of a coccinellid and by garden warblers (*Sylvia hortensis*). On a warm afternoon in October the author observed the invasion of a grove of acacias by the sea by a swarm of *A. laburni*, which was possibly a return migration of the sexual forms.

6) *A. myosotidis* Koch (= *A. cardui* Linn.); apterous specimens were taken on thistle at Odessa on June 29; they were severely parasitised by a small braconid.

7) *Aphis* sp.?; a few apterous specimens and one winged form were found clustered round the corolla of *Nigella* on the seashore near Odessa.

8) *Aphis* sp.?; apterous specimens infesting the common *Euphorbia* of the Bessarabian Steppe.

9) *Cryptosiphum artemisiae* Buckton; apterous specimens were found under the leaves of *Artemisia* in July.

10) *Dryobius croaticus* Koch; on shoots from the stump of an oak tree, in July; it was accompanied by numerous ants.

11) *Schizoneura ulmi* Linn.; common on elms in Odessa in June.

12) *Tetraneura ulmi* De Geer; the galls characteristic of this species were found on elms in Odessa in July, but all were then empty.

MEANS  
OF PREVENTION  
AND CONTROL

1181 — Aclimatisation Experiments in Italy with the African Hymenopteron *Opius concolor*, a Parasite of the "Olive Fly" (1). — SILVESTRI F., in the *Bollettino della Società nazionale degli olivicoltori*, Year XII, No. 1-2, pp. 1-3 of Reprint. Rome, 1918.

From the end of October, 1917, to the first ten days of March, 1918, were distributed in various olive orchards of Apulia (Fasano, in the province of Bari), of Latium (Hadrian's Villa, near Tivoli) of Campania (Cannichio, Pollica, Castelnuovo Vallo, Vallo della Lucania, and Ceraso, in the province of Salerno), and of Calabria (Sambiase and Nicastro, in the province of Catanzaro), 3 260 specimens of *Opius concolor* Szépl., an endophagous braconid parasite of the "olive fly" (*Dacus oleae* Gm.) found in September and October 1917, in Tripoli.

The majority of the insects were distributed at Hadrian's Villa (1 250) and at Ceraso (1 000), localities particularly suited to acclimatisation experiments. The author feels certain that it will be possible to acclimatise this *Opius*, at least in southern Italy and the islands, and hopes that it will destroy *D. Oleae* sufficiently to reduce the damage done by the dipteran in the olive orchards. This, however, cannot occur till the hymenopteron

(1) See R. Feb., 1911, No. 637; R. Feb., 1914, No. 190; R. Jan., 1917, No. 115, R. Feb., 1917, No. 210. (Ed.)

is really acclimatised and if it finds in its new surroundings no enemy to hinder its multiplication.

**1182 - *Pachymerus quadrimaculatus* a Weevil Injurious to the Black-Eye Pea (*Vigna catjang*) in Trinidad.** — URICH, F. W., in the *Bulletin of the Department of Agriculture, Trinidad and Tobago*, Vol. XVII, Pt. 1, pp. 14-162 + Plates, Port-of-Spain, 1918.

INSECTS, ETC.  
INJURIOUS  
TO VARIOUS  
CROPS

Apart from slight damage caused by damp the chief injury to stored black-eye peas (*Vigna catjang*) is through attacks of the black-eye pea weevil (*Pachymerus quadrimaculatus*). In Trinidad this insect infests generally black-eye peas and cow peas imported from the United States and Venezuela. Recently harvested peas appear most subject to attack.

This weevil is well known to the inhabitants of the island who are so accustomed to it that most of them affirm the peas cannot be kept free from it as it is generated by the peas themselves. No effort is, therefore, made to control it, and as soon as the harvest is gathered it is sold and re-sold as quickly as possible, as the peas will not keep for more than three months.

The damage is done by the larva, which eats the seed, and continuous generations feed on it till it is unfit even for the insects themselves to live on. A small chalcid, always associated with the weevil, preys on the larva. This natural enemy is well known to the inhabitants of Trinidad, who think it the young stage of the weevil. It controls *Pachym. quadrimaculatus* to some extent.

The black-eye weevil in peas can be destroyed by fumigations with carbon bisulphide (5 lb. to every 1000 cubic feet for 24 hours), and if the peas are kept in a clean, weevil proof room or receptacle they will be free from attack. As soon as possible after the harvest the peas should be dried and kept out of reach of the parasite. They should be examined before storing, and, if any eggs of the parasite are found, they should be fumigated and then aerated.

Peas for planting should be specially treated, and if fumigation is absolutely necessary, it should not last more than 12 hours.

Sprinkling the peas with kerosene oil and rubbing this oil in, as well as salting, cannot prevent attack by the weevil.

A description of the adult insect and short summary of its life history are given.

**1183 - *Phthorimaea operculella*, a Microlepidopteron Injurious to Potatoes, New for Indiana, U.S.** (1). — TROOR, J., in the *Thirtieth Annual Report of the Purdue University Agricultural Experiment Station, Lafayette, Indiana, for the Year Ending June 30, 1917*, p. 40. 1918.

During June, 1917, several loads of potatoes reached the Indianapolis market from Australia. These potatoes were badly infested with the potato tuber moth (*Phthorimaea operculella*), which has caused serious

(1) See R., Feb., 1912, No. 437; R., April, 1912, No. 749; R., July, 1912, No. 1117; R., June 1913, No. 751; R., Nov., 1914, No. 1081. (Ed.)

damage in California but has never previously been reported from Indiana. Growers were immediately notified as many of these potatoes had been planted before the infestation was discovered.

1184 - *Oxycarenus hyalinipennis*, a Hemipteron Injurious to Cotton, in Italian Somaliland (1). — DEL GUERCIO, G., in *L'Agricoltura Coloniale*, Year XII, First Half-Year, No. 3, pp. 147-166 + 23 Figs. Florence, 1918.

Description of the life history of *Oxycarenus hyalinipennis* Costa, based on material from Italian Somaliland.

From the examination of the numerous cotton bolls received, it is quite certain that a great quantity of the eggs of the hemipteron are inside the bolls themselves, more or less close to the seeds on the surface of which they have been occasionally seen. The eggs are also laid on the bracts surrounding the bolls as well as at their base.

As the young *O. hyalinipennis* leaves the eggs laid in the bolls, they pierce the seeds to obtain food, as do all the following stages of the insects. Those larvae that hatch outside the bolls attack the basal walls and thus obtain nourishment.

As regards enemies of this hemipteron, in the absence of other insects, the author has found in the viscera of nymphal and adult *Oxycarenus* Sporozoa which he places provisionally with the Eimeridae and considers as new to science under the names of *Pissidocystia oxycarenidis* n. gen. and n. sp., and *Valvicystia rhopaloides* n. gen. and n. sp. At the same time the author observed coloured parasitic corpuscles in these Sporozoa which he suspects are Amaebosporidia.

1185 - *Nysius ericae*, the False Chinch Bug, Injurious to Sugar Beets and Cruciferous Garden Crops in the United States. — MILLIKIN, F. B., in the *Journal of Agricultural Research*, Vol. XIII, No. 11, pp. 571-578 + 1 Fig. + 2 Plates. Washington, June, 1918.

This paper gives a morpho-biological description of *Nysius ericae* Schilling (= *N. angustatus* Uhler), commonly known as the false chinch bug. This insect has long been recognised as a serious pest, especially in the semi-arid districts of the United States. It damages seriously sugar beets and cultivated cruciferae, settling upon them suddenly in enormous quantities and sucking so much sap that the plants wilt in one or two days.

The observations were made at Garden City, Kansas, from 1913 to 1916 and, during the last year, also at Wichita.

1186 - *Aleurocanthus woglumi*, a Hemipteron Injurious to Various Cultivated Plants, in Cuba (2). — CARDIN, P., in the *Revista de Agricultura, Comercio y Trabajo*, Year 1, Vol. 1, No. 3, pp. 128-130 + 2 Figs. Havana, 1918.

*Aleurocanthus woglumi* ("mosca prieta") threatens to become one of the greatest pests of Cuban agriculture. Oranges, lemons and other species of *Citrus* are attacked most commonly, being the first upon which

(1) See R., March 1913, No. 203; R., May, 1916, No. 590 (Ed.)

(2) See also R., Nov 1916, No. 1217; R., Dec. 1916, No. 1347; R. Aug. 1918, No. 933. (Ed.)

the hemipteron appears. From the great quantity of *A. woglumi* on the oranges of a given locality the intensity of the attack in that locality can be judged. The insect also attacks coffee, *Psidium Guajava*, *Mangifera indica* and an increasing number of other useful plants.

The author, using *A. woglumi* as an example, calls special attention to the necessity for limiting the trade in plants and controlling it in such a way that suitable officials can find out where newly imported plants are placed.

The history of the "mosca prieta" is a very typical case showing the results of free importation of and trade in plants. The insect in question, apparently a native of India, was introduced from that country with branches of *M. indica* into Jamaica, with the object of propagating choice varieties of that fruit tree by grafting. About 10 years ago, it seems to have appeared in the district of Guantánamo, introduced from Jamaica, on account of the great trade with that island and the region of Guantánamo and Santiago de Cuba.

While attempts were being made to control the insect in the region of Guantánamo, it appeared in November, 1916, in Vedado, probably brought on cuttings of the varieties of eastern *Mangifera* so much sought for in that country. Later it was reported from Hoyo Colorado, where it had been introduced with plants from Vedado. Already the pest has begun to spread in the neighbourhood of Havana, extending to Calabazar and Rancho Boyeros which is the south-eastern zone and where *Citrus* plants are most cultivated.

Owing to various causes the development of the hemipteron is limited:—dry weather and wind are the most efficacious, while heavy rains, ants in Guantánamo, a small spider and, according to recent observations, even *Chilocorus cacti*, are beneficial. In Jamaica the insect is attacked by a fungus—*Aschersonia*—and experiments are now in progress at the Agricultural Station of Santiago de las Vegas to utilise this control.

As artificial means of control soap emulsions and solutions are used; the best is that made of whale oil and potash soap, as it is so easily prepared.

## INJURIOUS VERTEBRATES.

1187 - *Bacterium murisepticum*, the Specific Agent of an Infectious Disease of Field Mice (*Pitymys savi*), in Apulia, Italy (1).—MORI, N., in *Atti del R. Istituto d'Incoraggiamento di Napoli*, Ser. VI, Vol. LXIX, pp. 7-16. Naples, 1918.

In the beginning of August, 1916, the author observed a serious and hitherto undescribed natural infection of field mice (*Pitymys savi*) from Ascoli Satriano, Foggia, where these rodents had greatly decreased in number.

A microscopical examination showed the presence in the blood of in-

(1) See R. April, 1917, No. 396. (Ed.)

fected mice of a bacterium, which the author isolated and considers to be the specific agent of the infectious disease observed. This bacterium has been identified as *Bacterium murisepticum* (Flügge) Mig., and the author describes its microscopical, cultural, biochemical and pathogenetic characteristics which have so far been studied.

In view of the value which this bacterium may have in the control of field mice, the author made experiments with it in fields infested with mice at Foggia, Torremaggiore and Pietra Montecorvino. Six or eight days after spreading on the soil small pieces of bread containing cultures of the bacteria or after spraying the plants round the mouse holes with broth of the cultures, a more rational and economical method, there was a marked decrease in mice in the places treated, followed by their complete disappearance. Sometimes the infection spread to untreated districts.

1188 — Encouragement in the Growing of the Castor-Oil Plant in Indo-China. — *Feuille d'Informations du Ministère d'Agriculture*, Year XXIII, No. 35, p. 8, Paris, August 27, 1918.

LEGISLATIVE  
AND  
ADMINISTRATIVE  
MEASURES

In order to encourage the cultivation of the castor-oil plant in Indo-China, the Governor General of the Colony issued a decree dated February 16, 1918, regulating the issue of advances to castor-oil plant growers for the duration of hostilities.

By this decree the advances may be issued in the form of seed or loans. The borrower must undertake to sell to the Supply Service the whole castor-oil crop grown on his land for the cultivation of which the advance was made. The Administration ascertains that the sums advanced are devoted exclusively to the cultivation of the castor-oil plant and verifies the condition of the crops. Supervision may continue until the grower has discharged his whole debt. A maximum is fixed for the advances made for acreage already in condition to be cultivated, and another higher one for land which has to be prepared.

1189 — Measures Taken by the Administration in Indo-China to Promote the Development of Sericulture. — See No. 1264 of this *Review*.

1190 — Native Agriculture in Cochinchina. — QUESNEL, P., in *Congrès d'Agriculture coloniale, Gouvernement général de l'Indochine*, Saigon Series, *Bulletin* No. 1, 46 pp. + 1 Plate. Saigon, 1918.

DEVELOPMENT  
OF  
AGRICULTURE  
IN DIFFERENT  
COUNTRIES

The Author (Civil Service Administrator and Inspector of Political and Administrative Affairs) draws attention to the fact that Cochinchina is a purely agricultural country with, it may be said, one crop — rice. Of

The Author (Civil Service Administrator and Inspector of Political and Administrative Affairs) draws attention to the fact that Cochinchina is a purely agricultural country with, it may be said, one crop — rice. Of

LEGISLATIVE  
AND  
ADMINISTRATIVE  
MEASURES

DEVELOPMENT  
OF  
AGRICULTURE  
IN DIFFERENT  
COUNTRIES

the 20 provinces of the colony, only 5, situated in the East (Basia, Bienhoa, Thudaumot, Tayniuls and Giadinh), are provinces in which rice can only be grown in the valleys; the rest of the land, more or less high, is covered with forests or bare plains on which stock find a scanty pasture. In these provinces, in either grey or red soil, are found the rubber plantations and it should be possible to grow other crops there as well.

In the 15 other provinces situated in the Delta of the Mekong, Vaïco or the Saigon River, rice is practically the sole crop. The natives only grow other products as secondary crops, on land sufficiently high to be free from floods, on the banks of the canals and the "giongs", large banks of sand formed by the sea. Coconut and betelnut are cultivated along the waterways, where the houses generally are, but only on a small scale.

Of a maximum of 3 500 000 inhabitants there are 240 000 Cambodians, 153 000 Chinese, 31 000 Mois (savages), 6 800 Malays, and 71 000 Minh-huongs (half-breeds of native and Chinese parentage). There are some hundred foreigners — Indians, Japanese, Burmese, Arabs, Bengalese. Of the 153 000 Chinese living in Cochin-China, 22 000 are at Saigon and 75 000 at Cholon-ville. There are 35 000 Annamites at Saigon and 38 000 at Cholon-ville. If the Minh-huongs are reckoned in with the Annamites there are 2 975 000 Annamites and 431 000 other Asiatics. This only makes 3  $\frac{1}{2}$  million, but it must be remembered that many natives, like the Chinese, live without being registered anywhere so as to avoid paying taxes and, for this and similar reasons, the statistics supplied by the villages are always below the actual ones.

The author studies briefly these different classes of the population and shows that, without considering the Chinese, who are foreigners, the Annamite adapts himself best to our civilisation and our cultivation, that the Moï, although a savage, would also adapt himself well were it possible to get into closer touch with him, and that it is the Cambodian whom it is most difficult to touch, chiefly because of his purely buddhist education. The author then studies the development of the question under two main headings: — 1) agriculture properly speaking; 2) labour.

## I. AGRICULTURE PROPERLY SPEAKING.

*Present state of agriculture in Indo-China.* — The principal crop of Cochin-China is rice of which numerous varieties are cultivated according to the soil, its composition, position, and the quantity and the nature of the waters it receives during the rainy season. The area under rice increases each year because there is still much available uncultivated land in certain parts of the colony. As a rule this land is unfit for cultivation and valueless as a result of the stagnation of the water which often causes an excess of alum. Where, however, the Administration builds a canal, this land gradually becomes of value, the excess of injurious alum being carried into the canals by the surface waters (rain, floods). In a general way it may be said that the clay soil of Cochin-China contains alum to a

more or less marked extent ; it occurs everywhere, in the low South-West regions and in the high forest districts of the eastern provinces. .

With the exception of the eastern provinces, it may be said that all Cochin-China is one vast rice field, already planted or about to be so. Rain falls pretty regularly each year from May or June to October or November. It is usually early in the East and becomes later as the Gulf of Siam is approached, so that the harvest is earlier in the East and allows a large part of the population to go for the harvest to the western provinces, where labour is generally insufficient on the large estates.

In September or October, at the time of transplanting, the floods come in addition to the rain. The muddy waters of the Mekong spread more or less rapidly over that part of Cochin-China which borders on Cambodia. In the rest of the country, which is lower, the tides penetrate inland, bringing with them fertile mud.

The harvest is generally sure in Cochin-China ; it is sometimes more, sometimes less fine, even average, but there is no danger of famine. As rice forms the basis of the diet of the natives, Cochin-China largely supplies the food requirements of its population. In certain provinces (Chaudoc, Longxuyen) maize-growing has been started and tends to develop because the grain ripens and may be cut in three months, just as the first rains are beginning. It may, therefore, be grown in many rice fields near water-courses, so that it may be easily watered, and the same land may yield two crops of about equal value.

In 1915-16 Cochin-China produced 2 188 000 metric tons of paddy, in 1916-17, 2 350 000 tons. About 1 100 000 tons are kept back for local consumption and seed, the remainder is exported. Each year the harvest improves as a result of improved cultivation.

*Agricultural products exported at the present time.* — A table is given of the exports in 1914, 1915, 1916 and 1917. These products are :— rice (export about 922 259 metric tons in 1914 and 449 565 metric tons in 1917), paddy (approx. 41 482 metric tons in 1914 and 3 986 tons in 1917), cargo (approx. 25 181 metric tons in 1914 and 49 803 tons in 1917), rice bran (approx. 146 608 metric tons in 1914 and 72 605 in 1917), meals (approx. 159 944 metric tons in 1914 and 59 872 in 1917), maize (approx. 30 938 metric tons in 1914 and 7 485 in 1917), kidney beans (13 860 lb. in 1914 and 37 770 lb. in 1917), other dry leguminous seeds pepper, cattle (650 metric tons in 1914 and 100 in 1917), poultry, copra, peanuts, sesame and other oil-yielding seeds, fresh coconut, coconut oil, rubber (401 060 lb. in 1914 and 885 122 lb. in 1917), wood charcoal, kapok, various cakes, silks, silk wastes, ox hides, pig bristles, feathers, eggs (679 327 lb. in 1917), honey, feathers for fans, lard, castor oil.

*Labour devoted to cultivation.* — The different methods of farming, varying in each province, the different systems adopted by large land-owners to keep the workmen on their estates, to pay them, to advance them money and grain, are all reviewed. The expenses are fairly heavy as compared with the yield, but nevertheless the growing of rice by the present day methods yields a good profit. Many of the natives live well and give

an impression of ease and comfort very different from the poverty found among the natives of Tonkin and Annam.

*Yields per acre.* — **RICE.** — The yield varies from 80 to 100 *gia* for the average ricefields, or, 14.6 cwt. to 18.3 cwt (1 *gia* = 50.6 lb.) In certain soils it is as much as 120 or 150 *gia* (22 to 27.5 cwt.) and in poor soil, especially in the eastern provinces, may be as low as 20, 30, or 50 *gia* (3.7, 5.5 or 9.2 cwt.).

**MAIZE.** — Yields a profit in the province of Chaudoc about equal to that of rice.

**TOBACCO.** — This crop is being developed. It is grown mainly in certain parts of the east. The tobacco has a peculiar flavour and, for that reason, is only used by the natives and is consumed entirely in the country. The province of Giadinh yields the two best qualities of tobacco: — 1) Govap tobacco, the most appreciated by the natives, 2) Hocmon tobacco. One acre yields approximately 1943 cakes of govap tobacco weighing 300 gm. each, or 9.6 cwt.; the sale price is \$ 35 (1) per 100 cakes or \$ 680 with a profit per acre of \$ 85. One acre yields about 1217 cakes of Hocmon tobacco, weighing about 8.3 cwt. and selling at \$ 29 per 100 cakes, or \$ 400, the profit per acre being \$ 72.

**SUGAR CANE.** — Sugar cane is grown over about 11 000 acres in the eastern provinces. The species most widely grown for sugar production in this district are yellow cane, called "mia-vang", planted in low, rich soils, red cane, called "mia-ly", grown in rich, moist soils, and small cane, called "mia-lau", grown in high, dry soils; "mia-vang" yields 17.5 tons per acre and sells at \$ 265; "mia-ly" yields 11.5 tons per acre and sells at \$ 226; "mia-lau" yields 9.5 tons per acre and sells at \$ 111; the cultivation of this last variety is decreasing.

**PEANUTS.** — 30 to 32 *gia* per acre. Green peanuts weigh 26 to 33 lb. per *gia* and dried ones 22 to 24 lb. The sale price is approximately \$ 0.60 to \$ 0.65 =  $0.65 \times 30 =$  \$ 19.50 (for 30 *gia*) per acre.

**SWEET POTATOES.** — 20 *gia* of 48 to 50 lb. on an average; \$ 0.80 approximately, or \$ 16.

**MANIOC.** — Approximately 6.7 tons per acre. Sale price \$ 1.90 per *picul* of 132 lb. or \$ 217 per acre (a net profit of \$ 121).

*Possible improvements.* — The ploughs seem suitable to the nature of the land. Cochín-China rice is at least equal in food value to the best varieties of Japan, Java or Burma, but is less fine. It is, therefore, necessary:—

1) That the natives harvest so as to avoid any moistening of the sheaves because the rice often ripens before the soil of the field is quite dry. The sheaves are laid on the ground in small heaps so that the upper ones do not come in contact with the water, but the lower ones become wet and the grain spoils.

2) That the crop, which is usually threshed in the field, be brought in so as not to be wetted by late rains.

(1) 1 Indo-Chinese silver piastre (\$) = 2s. 3d. at par. (Ed.)

3) That the natives be provided with sorters so that they may set the finest grain apart *a*) for sowing, *b*) for selling, keeping the remainder for local consumption. In this way the natives would be able to select the grain easily and rapidly and supply better qualities with a higher yield.

According to the native nomenclature there are numerous varieties of paddy which, with the exception of the round grain and long grain varieties, are very difficult to differentiate. They are similar rices which have become slightly modified according to the nature of the soil in which they are grown. Sorting the grain would reduce these numerous varieties to a small number, taking into consideration the species with round or long grain, early rice and mid-season rice, and the nature of the fields, high or low, swampy or not. The swamp and semi-swamp rices of Chaudoc and Longxuyen form a very interesting distinct variety, the cultivation of which has been greatly improved by the natives who have produced swamp rices with practically none of the red grain which detracts so largely from their value. Good, inexpensive sorters should, therefore, be supplied. If selection of the good grain were combined with the rooting up of foreign varieties the quality of the grain would be rapidly improved.

4) The natives cut the rice sheaves by hand with a sickle at mid-height. A large quantity of stubble is thus left. Animals are first pastured in the field, but when they will not eat the straw because it is too dry advantage is taken of the strong winds of the dry season to burn it. The ashes obtained are of small advantage to the soil, especially as the wind carries many of them far. It would appear more advantageous not to burn the culms but to plough them in. They would decompose rapidly in the water-soaked soil and the roots of the new plants would derive benefit from them.

5) Fertilisers have been recommended to improve the yield, but the question is very complicated. The natives are poor and, generally, have few savings, living from hand to mouth, so that any fertiliser supplied must be cheap. The yield of the Cochin-China rice field is low when compared with those of Java. Cultivation is extensive because free land is not lacking and will not lack for a long time. More than double the quantity necessary for local consumption is produced. If it were possible to obtain a cheap fertiliser it is not certain that the benefit obtained would pay the expenses. In Cochin-China, where the Mekong River is not dammed, as is the Red River, in Tonkin, the whole country is flooded naturally in September and October. The waters, charged with fertilising mud, spread over the whole country, and the natives, by a very simple system of gutter-stones and gaps in the banks of the rice fields, make the waters penetrate far inland. The rice plants act like innumerable sieves and filter the muddy water, which, losing the rapidity of its current, deposits the mud on the soil. Fertilisers spread on these fields full of water would dissolve very rapidly and be largely carried away by the waters in the canals and ditches, or each field would have to be well shut in and would no longer benefit by the floods and the movement of the fertilising waters. Would there be any appreciable advantage to the

natives, for whom nature works, for the floods are rarely heavy enough or sufficiently prolonged to damage the crop. The natives profit more than they suffer.

6) It also appears premature to use machines for cultivation. The natives have adapted their tools to the soil and the nature of the plant they cultivate. European machines are too heavy to use in a soil which only dries and hardens when nature allows it to do so. The natives use a hoe, plough and wooden roller. The rice is generally threshed in the field in large wide-mouthed baskets about 6 ½ feet high, made of bamboo laths plugged with earth. As the grain drops easily, the sheaf is beaten on a sloping bench placed inside the basket; the grain drops to the bottom and is collected in baskets. To carry the rice sheaves to the farm a sledge drawn by oxen or buffaloes is used. This sledge passes everywhere, making gaps in the embankments of the rice fields. This material is simple, easily made and repaired, and adequate.

The only improvement required at present is that the Annamites should select their seed so as to prevent degeneration of the plant and decrease in yield. For this purpose they should be supplied with good, cheap sorters.

Each year Cochin-China receives from Cambodia, Laos and South Annam live stock to replace that which has died or to meet the requirements of the increased population. The demand has become yet greater since the formation of large rubber plantations which often require large herds for ploughing or fertilising purposes.

*Breeding.* — Cochin-China is not a breeding country and probably never will be on account of the floods in the west and the short grass produced by the poor, dry soils of the East during the dry season.

*Factors favourable to the development of native agriculture.* — Agriculture has hardly made any progress in the colony, it has developed in acreage only, not in yield, but in this sense has developed considerably. This is due to the reclaiming of immense uncultivated plains by digging canals with dredgers. Colonisation by Europeans has also increased.

Agriculture will develop more and more if numerous roads and canals are built. The regulation of labour (decrees of March 8, 1910 and May 20, 1913), largely imported from Annam or Tonkin, less from Java, has facilitated the establishment of rubber plantations in the East. The decree of April 13, 1909 concerning native workers on farms has been of more use to the French colonists of the West. The granting of land under special conditions with certain advantages has favoured both native and European colonisation.

Native agriculture (special reference is made to rice, all the other crops being secondary as compared to it) is developing normally under the effects of several causes :—

1) Some administrative :— digging numerous canals with dredgers, good maintenance and improvement of the natural and artificial transport ways already existing, etc. ; the greatest attention is being given to this.

2) The other natural :— the increase of the population which now

numbers approximately 3 500 000 and increases by about 100 000 annually.

## II. LABOUR.

As the rule the natives are both farmers and fishers ; in the wooded districts they are also foresters. Only the Moï is a woodman in particular and cultivates barely enough for his requirements.

Up to the present the labour question for the crops of Europeans has not become acute. In the western rice fields the decree of April 13, 1909 concerning agricultural labourers makes it easy for the colonists to obtain labour. In the rubber plantations of the East the decrees of March 8, 1910 and May 20, 1913 regulate the connections of the planters with the numerous workmen they are bound to employ, mostly in distant and unhealthy districts. They not only deal with foreign labour, but also with Indo-Chinese labour. Some people have brought over Javanese, most bring men from Annam or Tonkin, the latter being acknowledged to be better than those from Annam. By employing also the natives and, in some districts the Moïs, the planters have been able to obtain the necessary labour.

The two decrees are to be fused into one decree more suited to the present requirements. This modification has been found necessary as a result of certain difficulties which arise from time to time in some plantations. It will provide for an inspection of labour which will probably be entrusted to the Inspector of Political and Administrative affairs. It also provides for fixed salaries, the form of work, assistance and care in the case of sickness, boarding, feeding, water-supply, etc. On the whole the planters (less in the West, because it is healthy) have done their best for the comfort of their workmen. Rewards are given to good and old labourers, houses of a more or less permanent character of clay or bricks roofed with tiles have been built for them and their families. Drinking water is supplied, there are ambulances and hospitals, markets have been formed so that they may supply themselves without difficulty, even amusements are supplied at certain times of the year on the occasion of their religious festivals, theatrical companies, and cinemas.

There as elsewhere if the natives are comfortable they ask nothing better than to remain and be re-engaged. The labour on a plantation represents a large capital and the better it is, in better condition is the plantation and, consequently, more productive. It is in the interest of conscientious planters to look after their workmen and treat them well. On the large western agricultural estates the labour changes but little as a rule ; the conditions remaining the same the workman show no desire to go, and remain on the estate. Only those go who are badly treated or who, by nature, are fond of change and cannot settle in one place.

There is, however, no doubt that the labour in the country is inadequate to the development of the plantations in the East ; imported labour will be needed more and more. If the development in the East continues as

at present great attention will have to be given to the importation of labour or it will become a real danger to the agricultural settlement of the West, where labour is already insufficient. The importation of labour must be facilitated but, in the author's opinion, only labour from Indo-China, Tonkin and Annam should be used. Any kind of work may be entrusted to the Annamite if he is correctly approached. He is a product of an old civilisation which has developed without interruption and there is no doubt that he is destined to colonise all Indo-China.

**1191 — Foods of Tonkin.** — CHEVAST, C., in *Congrès d'Agriculture coloniale, Gouvernement Général de l'Indochine*, Hanoi Series, No. 2, 17 pp. Hanoi-Haiphong, 1918.

In these notes which form a complement of the "*Catalogue des Produits de l'Indochine*, Vol 1, *Produit alimentaires*", the author (Inspector of the Agricultural Services, Keeper of the Agricultural and Commercial Museum) reports the foods peculiar to Tonkin which are suitable for consumption in France.

**I. — VEGETABLE FOODS — Rice.** — Tonkin can export an average of 200 000 metric tons of rice and paddy. Of this quantity the Tonkin rice-fields at Haiphong can supply 9 to 15 000 tons of polished (table) rice. The annual production could reach 30 to 35 000 metric tons.

**Maize.** — In 1913, Tonkin exported 53 000 metric tons, in 1915 only 23 454 tons, and in 1916 5500 tons. The decreased exportation is due to the rapidly increasing local consumption.

**Kidney beans.** — Their cultivation will be intensified in Tonkin.

**"Mungo peas".** — The small French bean has proved suitable as a food in Europe cooked as other beans and prepared as "purée" so as to remove its outer coat; it has a vegetable taste peculiar to itself. Tonkin could supply nearly 500 metric tons of these beans annually, the other countries of Indo-China about 700 tons together at an average price of 6 to 7 *piastres* per 100 kg. (220 lb.).

**Various dolichos.** — Little liked in Europe because of their unpleasant vegetable taste, but perhaps suitable for livestock. In Tonkin alone an annual production of 1000 metric tons at \$4.50 to \$5 per 100 kg. may be relied on.

**Soya.** — The annual yield in Tonkin is approximately 1 000 metric tons selling at \$8 to \$9 the 100 kg.

**Cereals.** — In the Yunnan district where the climate is temperate, the author has as yet been unable to determine the amounts available or their value.

**Manioc (slices).** — There are two species in Tonkin, sweet manioc and bitter manioc, both largely cultivated. In normal times the dried slices are sent to France. About 100 metric tons of slices are available annually at an average price of 4 *piastres* per 100 kg.

**Manioc paste ("Ho-Tieu").** — A product made in Annam; 14 *piastres* per 100 kg.

**Bean vermicelli ("Song-Thân").** — In Annam 176 000 lb. per year are made. This product is distributed by Chinese buyers at Singapore, Hong-

Kong, Bang-Kok. It is an excellent dietetic food which could be used especially in hospitals.

*Flours.* — Tonkin has no large flour factory. The by-products of decortication (factory flours) are only usable as mash for animals. In Cochinchina the average amount of the exportation of these flours from rice factories is 128 000 metric tons.

*Arrowroot starch.* — In Tonkin this is prepared from two plants — *Maranta arundinacea* ("Koang-Tinh") and *Costus speciosus*. Both these plants are being grown to an ever-increasing extent in the Delta and in certain provinces of Tonkin. The starch yield of the roots is 24 %. Arrowroot starch is very suitable as a food for infants and convalescents. The price is about \$ 0.30 per kg. of starch.

*Sweet potato starch.* — The "Khoai-Lang" sweet potato with its 5 or 6 local varieties is much grown in Tonkin. The starch yield of the tubers is 15 %, the selling price \$0.30 per kg. of starch.

*Sweet potato slices.* — A local industry. These slices appear to yield 34 to 40 % of their weight in alcohol.

*Yam (Dioscorea) starch.* — Five or six species of yam are grown in Tonkin. The starch is very nutritious. There are no fixed prices.

*Taros (Colocasia).* — There are several species in Tonkin. The average price of the roots is \$0.40 a load of about 55 lb.

*Annam and Tonkin spathe.* — The Annam species "Khoai-Nua" is represented by *Amorphophallus campanulatus*. Tonkin spathe ("Khoai-Na"), *Amorphophallus Rivieri*, is much used as a food for pigs.

*Tacca.* — The plant ("Nua") is not cultivated in Tonkin, but in Central Annam occurs frequently enough to be taken into consideration. It yields as much as 30 to 33 % of food starch.

*Bulb dolichos.* — The tubers cost from \$0.80 to \$1 a load.

*Kondzou.* — The tubers are made into starch.

*Sago.* — In the high districts of Tonkin the mountaineers obtain the pith of certain palms such as "Cây-Dao" (*Phoenix farinifera*) and "Cây Moc" (*Caryota*). The manufacture is limited to the very small demand. The product should be sought in south Indo-China where *Metroxylum*, which produce good sago, is fairly common.

*Vegetables: Bamboo shoots* ("Mang-Tre-Khê"), \$0.32, \$0.30 and \$0.25 a pound of 600 gm. according to the three qualities.

*Dried mushrooms:* "Mộc-nhi" and "Nâm-huong".

*Coffee.* — Small production.

*Tea.* — The European colonies of Tonkin and Annam can supply an average of 500 metric tons of prepared tea.

*Sugar.* — Tonkin is still dependent on Annam.

*Dried spices.* — \$0.50 to \$0.60 the kg.

*Camellia oil.* — Tonkin and North Annam can produce about 10 000 kg. annually. The seeds sell at \$5 to \$6 the 100 kg., the oil at \$24 the 100 kg.

*Peanut oil.* — Tonkin produces few peanuts; south Indo-China pro-

duces far more. The average exports from Indo-China from 1910 to 1916 inclusive were 368 000 kg. of seed and 104 000 kg. of oil.

*Sesame oil.* — Sesame is well cultivated in Tonkin but yields little oil there (about 3 000 kg. were exported to China in 1914). In the rest of Indo-China the production is much greater. In Tonkin the seeds sell at \$13 per 100 kg. and the oil at \$20 to \$22 to 100 kg.

*Coco-oil.* — Coconut is rarely cultivated in Tonkin.

II. — ANIMAL PRODUCTS. — *Cattle.* — Tonkin receives 20 000 head of cattle annually from North-Annam and from 4000 to 5000 head from the Chinese province of Quang-si. A fairly large cold store has recently been erected at Bê-n-Thuy, near Vinh (Annam) for dealing with frozen meat supplied from the livestock of North Annam and the neighbouring provinces of Laos.

*Pigs.* — As a result of floods the stock of pigs in Tonkin has decreased markedly; this accounts for the appreciable rise from \$0.32 to \$0.45 of pork on the Hanoi market. Nevertheless the breeding of young pigs for market is actively carried on in the mountains and, if the floods do not interfere again, it will not be long before the country is stocked normally. It is estimated that there are over a million pigs in Tonkin which is better stocked in this respect than any other country of Indo-China. The annual consumption of the town of Hanoi may be placed at 32 000 head. Estimating the total consumption of Tonkin to be 400 000 head, it should be possible to export a considerable amount of pork to France.

*Pig's fat; lard.* — The maximum quantity Tonkin can produce is 15 400 lb. of lard per month.

III. — SEA PRODUCTS. — *Dried and salt fish.* — In 1914, 1 337 600 lb. of such fish was exported from Tonkin to China. In a good year the sea catch of Tonkin gives a figure to which must be added from 100 to 120 metric tons of various products (holothuria, sharks' fins, etc.).

*Dried shrimps.* — A very substantial food; 26 400 lb. are exported to China annually.

*Fish and shrimp pastes.* — These pastes could not replace the very expensive cod's roe, obtained from Norway, but could at least be mixed with it. As much as 308 000 lb. (the export to China in 1910) may be produced annually.

*Prepared holothuria.* — Indo-China produces fairly large quantities; each year Tonkin exports about 50 metric tons to China. They sell at \$15 to \$20 the *picul* of 60 kg. (132 lb.).

*Nuoc-mam.* — A fish food made in three qualities selling at \$2.5, \$2 and \$1.50 per petroleum tin (about 39 lb.)

1192 — *Contribution to the Study of the Culicidae of French Guiana.* — LEGER, M. (Institute of Hygiene of Cayenne), in the *Bulletin de la Société de Pathologie Exotique*, Vol. XI, No. 5, pp. 397-400. Paris, 1918.

Diseases transmitted by Culicidae are of the greatest pathological importance in French Guiana and have often proved serious obstacles to colonisation; malaria, filariasis and yellow fever hindered the economic

development of the country in the 19th century. The species of Anophelidae and Culicidae and their distribution throughout the colony are given. Only two species of Anophelidae are known — *Anopheles (Cellia) argyrotarsis* Desv. and *A. (C). albimanus* Wied. (*cubensis* Agr., *albipes* Theob.); the second species is the more common.

The *Culicidae* identified by the author at the Institute of Hygiene of Cayenne are : — *Culex fatigans*, *C. digitatus*, *C. mathisi*, *C. flavipes*, *Culicella taeniorhynchus*, *Taeniorhynchus fasciolatus*, *Mansonia amazonensis*, *Melanoconion atrotum*, *Stegomyia fasciata*, and *S. luciensis*, a variety of the preceding one.

1193 — The Tatu (*Tatusia novemcincta*), Host of *Schizotrypanum cruzi* the Agent of "Minas Meningitis", in Brazil. — *Chacaras e Quantas*, Vol. XVII, No. 6, p. 450. São Paulo, June, 1918.

In 1912, at Lassance, Minas, Dr. CARLOS CHAGAS, director of the " Instituto Osvaldo Cruz " at Manguinhos, Minas-Geraes, Brazil, discovered that this armadillo or tatu (*Tatusia novemcincta*) is the primary host of the protozoan known as CHAGAS' protozoan (*Schizotrypanum cruzi*) which, when inoculated into man by *Triatoma (Lamius) megistus*, a sucking insect of the *Reduviidae* family, causes the very serious disease known in Brazil as " Minas meningitis " and " babeiro ". The acute form of this disease causes nervous trouble or meningitis (this especially in children), and its chronic form causes changes in the thyroid gland and cretinism.

The protozoan causes no disease in the tatu. When the insect, also known as " barbeiro ", sucks the blood of an infected tatu *Schizotrypanum cruzi* develops in its intestinal tube, and passes through to the salivary glands. When the insect bites man it inoculates him with the parasite.

" Minas meningitis " occurs only where tatus live. The carrier insect *Triatoma megistus*, has been found both in human dwellings (especially huts) and the holes of tatus. If these animals were destroyed the contagious illness would disappear. Furthermore, an enemy of poultry yards would also be suppressed.

1194 — I. Vitamines and Symbionts (1). — II. The Action of Symbionts on the Constituents of Fats. — BERRY, H. and PORTIER, P., in *Comptes rendus des Séances de l'Académie des Sciences*, Vol. CLXVI, I, No. 23, pp. 963-966. Paris, June 10, 1918; II, No. 25, pp. 1055-1057. Paris, June 24, 1918.

I. — After referring to the indispensability of vitamines in feeding, the authors give the results of the researches they carried out to ascertain if there is any relation between vitamines and symbionts (bacteria isolated from the tissues of normal animals).

A first series of researches showed that symbionts introduced into the vertebrate organism were perfectly tolerated, and caused no disorder or suppuration, and seemed to disappear rapidly from the circulatory system, tissues or serous membranes.

As these microorganisms were shown to be harmless, their possible intervention in the phenomena of metabolism remained to be proved.

(1) See R., October 1917, No. 926. (Ed.)

Young, but nearly full-grown, white rats were used as experimental subjects, then adult rats and finally pigeons. The rations given the subjects were such as would cause disorders of sub-nutrition after a certain length of time (seeds decorticated or sterilised at high temperatures for the pigeons; bacon or bacon fat sterilised at high temperatures, coagulated white of egg, salts and water for the rats). Controls received a ration composed of the same foods, but such as would not cause metabolic disorders (seeds with the seed-coats, unsterilised bacon or fat).

RESULTS. — 1) The experiments all confirm the chief results obtained by EYKMAN, GRYNs, FUNK, etc.:— loss of appetite, emaciation, locomotor troubles, paralytic phenomena, etc. A prolongation of the experiment led to death preceded by a very intense adynamic state and trophic disturbances in the rats.

When the animal suffering from nutritive deficiency (cared) was given a normal diet it continued to lose weight for a few days, but, under the influence of the vitamins in the food, the morbid symptoms gradually gave way and it recovered.

2) A cared animal, already intensely affected with the pathological phenomena already described, is taken and injected under the skin or in the peritoneum with a culture of living symbionts. After 24 to 48 hours, an extremely striking change takes place. The locomotory troubles vanish very rapidly; the animal soon recovers its agility and has a remarkable appetite, especially for fats; the loss of weight ceases, being replaced by a clear gain of weight.

These phenomena are still more striking with pigeons, which pass in a few hours from a complete adynamic state to an almost normal appearance in both walking and flying.

Repeated injections (always of 1 cc.) of the living cultures produce the same good results each time.

Thus the introduction into the organism of symbionts of appropriate origin and in suitable form, eliminates the nutritive deficiencies due to a diet lacking vitamins. The initial hypothesis was thus clearly verified by repeated experiments extending over several months.

The only objection that can be raised appears to be that the microorganisms injected act, as far as they are living, by the vitamins they contain and that any harmless bacterium could produce the same good effects.

It certainly seems that certain microorganisms (yeasts) contain vitamins but it should be noted that intestinal bacteria apparently do not contain vitamins since in nutritive-deficiency experiments disorders appear in spite of the abundance and variety of the intestinal flora. It seems remarkable that symbionts, normal inhabitants of the organism, can play the part of vitamins.

II. — The authors wish to show that symbionts can reproduce certain normal phenomena of animal metabolism, especially as regards the constituents of the fats.

Glycerine, which appears to be a source of sugar for the organism, is changed into dioxyacetone (triose [C<sub>3</sub>] sugar which easily changes to

hexose). On the other hand it can be probably shown experimentally that salts of  $\alpha$ -glycerophosphoric acid can be changed into salts of dioxy-acetone phosphoric acid in the same way.

Symbiotes can also carry out, *in vitro*, the  $\beta$ -oxidation that applies to fats of low molecular weight. On inoculating a sterile, neutral broth containing 1 % of  $\beta$ -oxybutyric acid, proteins and nitrates with these bacteria, the presence of acetone and acetic aldehyde may be detected after 3 weeks. Starting from butyric acid and using a similar medium to that described, the authors found acetone present in the culture solution; the other substances were not sought for. The presence of acetone shows the production, at a given moment, of the corresponding  $\beta$ -ketonic acid and that of acetic aldehyde shows that the fat molecule has been greatly broken down.

This is the first example, so it appears, of the carrying-out of the physiological process in question by means of microorganisms.

**1195 - Studies on Nitrogen Poisoning.** — Maignon, F., in *Comptes rendus des Séances de l'Académie des Sciences*, Vol. CLXVI, No. 22, pp. 919-922; No. 24, pp. 1008-1011; Vol. CLXVII, No. 2, pp. 91-94. Paris, June 3 and 17, July 8, 1918.

I. — INVESTIGATIONS INTO THE TOXICITY OF EGG ALBUMIN; INFLUENCE OF THE SEASONS ON THE SENSIBILITY TO NITROGEN POISONING. — MAGENDIE showed in 1816 that nitrogenous foods are indispensable to animal life; he also concluded they are insufficient in themselves as dogs fed on pure gelatine died from emaciation.

The author continued MAGENDIE's experiments and fed white rats on true albuminoid matter (egg albumin, fibrin, casein) of the highest possible purity. Commercial finely powdered egg albumin was made up into pills weighing 1 gram by the use of a weak solution of gelatine. To avoid demineralisation of the experimental subjects small quantities of mineral salts and bicarbonate of soda were added to the pills so as to keep the urine slightly alkaline and to prevent acidosis. The experiments led to the following conclusions:—

1) Egg albumin is incapable of supporting life and maintaining weight in the white rat;

2) White rats fed on egg albumin die rapidly of acute poisoning of the central nervous system in May and October, but succumb slowly from emaciation in August and January.

These facts make it possible to understand the seasonal character of the manifestations of certain nutrition diseases connected with nitrogen poisoning; such as eczema, rheumatic troubles, etc.

3) Acute albumin poisoning causes coma.

II. — A COMPARATIVE STUDY OF THE TOXICITY AND THE NUTRITIVE POWER OF FOOD PROTEINS EMPLOYED IN THE PURE STATE. — The investigations, similar to the preceding ones and also made on white rats, dealt with fibrin, casein and meat powder, this last substance being previously extracted with boiling water, alcohol, and ether. In spite of this treatment the powder still contained an appreciable quantity of fat in the form

of adipo-protein compounds. These proteins were given at discretion in 1 gm. pills to which had been added, as in the previous case, mineral salts and bicarbonate of soda to avoid de-mineralisation and acidosis.

The experiments showed that none of the proteins tested are capable alone of supporting life and maintaining weight in the white rat, even for short periods. The influence of seasons, so marked for egg albumin, is entirely lacking for the other proteins. The toxicity can only be estimated by the length of time the animal survives. From this point of view the proteins under consideration can be classed in the following order for the white rat :— egg albumin, fibrin, casein, the latter being by far the least toxic. Meat powder may be placed on a level with fibrin.

With fibrin, casein and meat powder death, in every season, is the result of exhaustion of the reserves, not of chronic poisoning. The animals die from atrophy after heavy losses in weight. The lesions caused by food poisoning are insufficient to account for death. Rats fed with casein or fibrin have, after some time, a very fatty liver, which may be recognised by its yellowish colour and thick, rounded edges. The microscope shows the presence of excessive internal fat. In the case of casein the excess is double that caused by fibrin. It is not present with egg albumin and meat powder. The length of time the animal survives and the facility with which the albumins ingested change to fat are closely related. Everything points to the fact that the fat formed prolongs the period the animal survives by decreasing the rapidity with which the reserves are exhausted, the death occurring only when the reserves of fat have practically disappeared, as if this substance were indispensable to the utilisation of the proteins ingested. As the influence of the seasons does not exist with casein and fibrin, it seems as if the presence of fat makes the organism less sensitive to nitrogenous poisons in spring and autumn.

III. — INFLUENCE OF THE SPECIES OF ANIMAL ON THE TOXICITY AND UTILISATION OF FOOD PROTEINS. — After having studied the poisonousness and nutritive value of food proteins, using the cat and dog as subjects, the author compares the results obtained with the two species, using egg albumin, casein and meat powder.

1) With *egg albumin*, a fixed weight is never maintained in either cat or dog.

2) With *casein*, the two species behave quite differently ; with the rat, a fixed weight is maintained with difficulty and death results from exhaustion rather than poisoning ; with the dog, on the contrary, the weight is easily maintained, but it soon clearly feels the toxic action, being unable to transform casein into fat so easily as does the rat.

3) With *meat powder*, a fixed weight, impossible to maintain with the rat, is easily attained with the dog.

The author interprets these facts as follows :— The dog, naturally a carnivorous species, adapts itself better to a purely protein diet than the white rat, a carnivorous and often vegetarian species. On the other hand, the nutritive value of a food is not of necessity connected with its poisonousness (as in the case of casein and the dog) ; the toxicity of a protein

varies from one species to another and seems to be in relation to the capacity they have of changing protein into fat. When this transformation capacity is reduced in a species, that species is much more sensitive to the toxic action, which affords a new proof of the important part played by fats in the utilisation of proteins.

**1196 - The Comparative Influence of Carbohydrates and Fats on the Utilisation of Food Proteins.** — MAIGNON, F., in *Comptes Rendus de l'Académie des Sciences*, Vol. CLXVII, No. 4, pp. 172-175 + 2 Tables. Paris, 1918.

As egg albumin alone can neither maintain a nutritive equilibrium nor a fixed weight, the author, using white rats as subjects, investigated the influence of added starch or fat on the properties of the albumin in question. He varied the relative proportions of the constituents of the two foods, albumin-starch and albumin-fat, and each day estimated the food ingested and every two days weighed the subjects in a fasting state. The observations obtained led to the conclusion that the addition of fat or starch compensates for the deficiencies of the egg albumin, but with unequal efficacy; the albumen is better utilised with the fat than with the starch, the mixture of 1 of albumin + 1 of fat giving better results than 1 of albumin to 1 of starch. When the rats were fed with the three nutritive elements, albumin, fat and starch, the mixture containing as much fat as albumin again gave the best results. The minimum of albumin required is 3 times less with fat than with starch.

The author observes that, in meat, the fat is present in a slightly lower proportion than albumin.

It may, therefore, be concluded that fats play an important part in the utilisation of proteins, and cannot be replaced by carbohydrates.

**1197 - On the Minimum of Sugar in the Diet and Hitherto Unconsidered Sources of Carbohydrates.** — BERRY, H. and PORTIER, P., in *Comptes rendus de la Société de Biologie*, Vol. LXXXI, No. 11, pp. 574-576. Paris, 1918.

The importance of certain amino-acids in the diet (1) and the question of vitamins have complicated the general problem of nutritive exchanges. The derangement of metabolism caused by shortage of carbohydrates during total fasting or abstention from carbohydrates has given rise to doubts as to the possibility of complete iso-dynamic substitution of carbohydrates by fat. The author's recent investigations appear to throw new light on the subject.

Rats subjected to a diet of coagulated white of egg, bacon or pure bacon fat, water and salts, maintain a fixed weight and show no appreciable illness, but acidosis sets in as soon as *the ratio of fat to albumin exceeds a certain proportion*.

The author explains this fact as follows:— at first sight it appears opposed to the classical results of abstention from carbohydrates, but a careful study shows that coagulated white of egg contains carbohydrates or substances which form these compounds (free sugar, glucosamine, etc. in

(1) On this subject see R. April and June, 1918, Nos. 442 and 658. (Ed.)

quantities of 8 to 10 gm. of these substances per 1000 gm. of fresh white of egg). On the other hand, the fat itself is a source of sugar; the glycerine may be changed into di-oxyacetone or triose sugar, and this last into a hexose by polymerisation (BERTRAND).

A diet composed of proteins and fat does, therefore, contain a certain quantity of carbohydrates of different origin so that there exists a *sugar minimum* just as there exists a nitrogen minimum. This minimum varies with the nature of the proteins, fat and sugars of the diet. A certain equilibrium between these factors is necessary to avoid metabolic disturbances.

**1198 - The Food Value of the Banana.**— PRESCOT, S. C. (Professor of Industrial Microbiology, Massachusetts Institute of Technology), in *The Scientific Monthly*, Vol. VI, No. 1, January, 1918, reprinted in *The Journal of the Board of Agriculture of British Guiana*, Vol. XI, No. 2, pp. 52-65 + 3 Tables. Demerara, April, 1918.

The banana is the principle source of carbohydrates in the diet of many tropical races, taking the place of the cereals and tubers of the diets of temperate zones. Numerous detailed investigations have shown the banana to give a larger unit yield in food material than wheat or any other crop. For this reason it must not be considered as a luxury but as one of the most important human foods, and should receive more consideration from physiologists and agriculturists than has hitherto been the case.

Many analyses have been made of the chemical composition of the edible portion of the fruit. The author gives the averages obtained by ATWATER and BRYANT (U. S. Department of Agriculture, Bull. No. 28, p. 71, 1906) which form a sort of general average of the composition of the different varieties (the banana usually eaten in the United States is the fruit of *Musa sapientum*):— Water, 75.3 %; protein, 1.3 %; fat, 0.6 %; carbohydrates, 22 %; ash, 0.8 %; calories per lb., 460.

An analysis of the ash made by the author gave the following results:— Silica, 2.19%; ferrous oxide, 0.18; lime, 1.82; magnesia, 6.45, sodium, 15.11; potash, 3.55; chlorine, 7.23; sulphur trioxide, 3.26; phosphoric acid, 7.68. The ash is, therefore, composed chiefly of phosphates, sulphates and chlorides of potassium, sodium, magnesia, and lime, i. e. salts which respond the best to the demands of the body. The banana contains all the substances necessary to maintenance, but its low protein and fat content as compared with the carbohydrate content do not make it possible for the banana *alone* to form a well-balanced ration. To remedy this defect it is sufficient to add milk or a small amount of meat to the ration.

The banana compares favourably with the best animal or vegetable foods; this is shown by a comparative table including widely-different foods. The analytical data given by ATWATER and BRYANT (*ibid.*, p. 68) for the potato are:— water, 78.3 %; protein 2.2 %; fat, 0.1 %; carbohydrates, 18 %; ash, 1 %; calories per lb., 385. These may be compared with the values given above for the banana, from which it is seen that the banana exceeds the potato by about 20 % in food value and calories.

It is commonly believed that the banana is indigestible if not cooked; this is only true if the fruit is insufficiently ripe and completely fallacious

for the completely ripe banana, as has been shown by many workers. The following figures which give the duration of *complete digestion* of various foods show that a ripe banana is digested more rapidly than the most common foods:—

Ripe bananas, 1 hour 45 minutes; vegetable marrow, 1 hr. 45 min.; onions 2 hr. 5 min.; beans, apples, 2 hr. 30 min.; green peas, 2 hr. 35 min.; oranges, 2 hr. 45 min.; oatmeal, 3 hr. 5 min.; roast mutton, 3 hr. 15 min.; boiled eggs, boiled potato, codfish, 3 hr. 30 min.; plums, 3 hr. 40 min.; nuts, 4 hr.; boiled beef, 4 hr. 15 min.; cabbage, 4 h. 30 min.; roast pork, 5 hr. 20 min.

The rapid digestion of the banana is caused by the fact that during mastication the carbohydrates are largely transformed to assimilable sugar in the mouth, and further transformation in the stomach requires comparatively little time. The banana is, therefore, not only richer in nutrients per unit of weight than many common foods, but is also more digestible.

For these reasons this fruit should be more largely consumed, especially under present conditions, when it might help to overcome the shortage of cereals and other carbohydrate foods. This is all the more easy as its production is abundant throughout the year, that it may be shipped long distances, may be eaten raw or cooked, as a fruit or a vegetable, and is one of the few foods the price of which has remained normal during the last years.

**1199—Foundation of a High School of Agriculture and Forestry in Indo-China; Prospectus of Subjects Taught.** — *Journal Officiel de l'Indochine Française*, Year XXX, No. 29 bis, pp. 689-694. Saigon, April 10, 1918.

AGRICULTURAL  
EDUCATION

The Governor General of Indo-China has issued a decree for the establishment in the colony of a High School of Agriculture and Forestry in order to train farmers and foresters capable of rationally managing the agricultural and forest lands of the country. A diploma will be awarded and will entitle the holders to enter the agricultural and forestry services of the colony. The different articles of the decree deal with the organisation of the school.

Entrance is by competition. The students must be not less than 16 years old and not more than 22 and must be able to show they are French subjects, under French protection, or Asiatic French citizens. They must also have one of the following qualifications: — “diplôme d'études complémentaires”, “brevet élémentaire” or “brevet supérieur de l'enseignement primaire”, “baccalauréat de l'enseignement secondaire”. The students receive a monthly maintenance grant.

The period of study extends over three years. The curriculum includes: 1) general instruction (1st year); 2) technical and professional instruction (2nd year); 3) special subjects (3rd year). The 1st year courses are attended by both agricultural and forestry students; they deal with physics, chemistry, botany, zoology, geology, agriculture, applied natural history, mathematics, mechanics, topography, book-keeping, horticulture and gardening.

The 2nd. year courses are divided into two distinct parts : — 1) theoretical part together with six months' practical work (economic botany, agricultural zoology, animal breeding, agricultural meteorology, agrology, rural economics, ethnography, and hygiene); 2) an essentially practical part lasting three months (cultivation of industrial plants, agrology, rural engineering, book-keeping and sericulture).

The 3rd. year is devoted to the study of special subjects. The students attend the courses and practical classes in a special school in Cochin-China. This school includes : 1) a museum ; 2) a demonstration farm with a model dairy ; 3) a model silkworm nursery ; 4) a bee hive ; 5) experimental and demonstration plots (rice, maize, coffee, tea, sugar cane, cotton, rubber, coconut) ; 6) laboratories (botany, chemistry, entomology, wood-testing) ; 7) a meteorological station ; 8) a tree nursery. At the end of the 3rd. year of study the students are examined in agricultural and forestry subjects. Each qualified student then works for a year either at an Agricultural Station (for agriculture) or at the Fuyen-Quang nursery, a sub-temperate forest (for forestry).

A detailed prospectus is appended to the decree.

## CROPS AND CULTIVATION.

### 1200 — Partial Correlation Applied to Dakota Data on Weather and Wheat Yield. —

AGRICULTURAL  
METEOROLOGY

BLAIR, T. A., in *Monthly Weather Review*, Vol. XLVI, No. 2, pp. 71-73. Washington, February, 1918.

In previous papers, the author showed for Dakota : —

1) The existence of a *positive* correlation between the total rainfall for May and June and the yield of spring wheat, the relative correlation coefficient  $r$  (1) being equal to  $+0.63 \pm 0.05$  in North Dakota and  $+0.59 \pm 0.06$  in South Dakota ;

2) the existence of a higher *negative* correlation between the total temperature for June and the yield of spring wheat ;  $r = -0.67 \pm 0.08$  for North Dakota and  $-0.73 \pm 0.07$  for South Dakota.

In addition to these two correlations the author calculated that between rainfall and temperature and always obtained negative values for  $r$ . In other words, to a wet May and June corresponds usually a cool June.

These preliminary data give rise to two interesting questions :

a) How much of the apparent relation between rainfall and yield is really due to the influence of rain and how much to the simultaneous action of temperature ?

b) How much of the apparent relation between temperature and yield is really due to the temperature and how much is due to the simultaneous action of rainfall ?

The two questions may be solved by the use of *partial correlation coef-*

(1) See R., February, 1918, No. 148, note at foot of p. 175. (Ed.).

*ficients* by calculating the correlation between two variable factors after the elimination of one or more other factors. In the present case, where there are three variables — rain, temperature, and yield — the partial correlation coefficient is represented by the formula:—

$$r_{\alpha\beta\cdot\gamma} = \frac{r_{\alpha\beta} - r_{\alpha\gamma} r_{\beta\gamma}}{\sqrt{(1 - r_{\alpha\gamma}^2)(1 - r_{\beta\gamma}^2)}}$$

Here the variables are represented by  $\alpha$ ,  $\beta$ ,  $\gamma$ . The terms  $r_{\alpha\beta}$ ,  $r_{\alpha\gamma}$  and  $r_{\beta\gamma}$  represent the *total* correlation between each pair of variables (e. g., between rain and yield, temperature and yield, etc.), and  $r_{\alpha\beta\cdot\gamma}$  represents the *partial* correlation between the factors  $\alpha$  and  $\beta$  after the factor  $\gamma$  has been eliminated.

If, using this formula, the factors rain, temperature and yield are represented by the letters  $p$ ,  $t$ , and  $y$ , the equations are:—

$$r_{py\cdot t} = \frac{r_{py} - r_{pt} r_{ty}}{\sqrt{(1 - r_{pt}^2)(1 - r_{ty}^2)}} \quad r_{ty\cdot p} = \frac{r_{ty} - r_{pt} r_{py}}{\sqrt{(1 - r_{pt}^2)(1 - r_{py}^2)}}$$

$$r_{pt\cdot y} = \frac{r_{pt} - r_{py} r_{ty}}{\sqrt{(1 - r_{py}^2)(1 - r_{ty}^2)}}$$

If the letters are replaced by their values, calculated by correlation tables, and the three equations resolved, the values given in the following table are obtained:—

	$r_{py}$	$r_{ty}$	$r_{pt}$	$r_{py\cdot t}$	$r_{ty\cdot p}$	$r_{pt\cdot y}$
North Dakota . . .	+ 0.61	— 0.45	— 0.38	+ 0.53	— 0.30	— 0.14
South Dakota . . .	+ 0.49	— 0.62	— 0.56	+ 0.22	— 0.48	— 0.37

It will be seen that the total correlation coefficient  $r_{py}$  between *rain-fall* and *yield* which in North Dakota is equal to + 0.61 and in South Dakota to + 0.49, is reduced to + 0.53 and + 0.22 respectively when the factor *temperature* is eliminated. A considerable part of the apparent effect of rainfall on the grain yield of spring wheat is, therefore, due to the simultaneous action of temperature. Similarly the coefficients for the effect of *temperature* only are — 0.30 and — 0.48 instead of — 0.45 and — 0.62.

The relation between the three factors under consideration is clearly seen. Moreover, the coefficients  $r_{py\cdot t} = + 0.53$  and  $r_{ty\cdot p} = - 0.30$  for North Dakota show the influence of rainfall to exceed that of temperature. This is the opposite to South Dakota where the coefficients + 0.22 and — 0.48 show the influence of temperature to be predominant. It is well known that the rainfall in May and June and the temperature of June are

not the only factors influencing yield. It is for this reason that the partial correlation coefficients considered, although high, are nevertheless far removed from unity ( $+1$  or  $-1$ ).

1200—**A Method Recommended in the Argentine for Avoiding Frost Damage to Cane Stools.** — ROSENFELD, A. H., in *Sugar*, Vol. XX, No. 5, pp. 182-183. Chicago, 1918.

In the province of Tucumán (Argentine) the early frosts which are frequent at the end of autumn or the beginning of winter (June 21) make it necessary nearly every year for planters to cut frost-bitten cane prematurely. Such cane contains more impurities and less saccharose than that cut at the end of July or the beginning of August. The bad effect of premature cutting is yet more marked on the crop of the following year. The stools cut in the middle or at the end of June begin to sprout very early in spring and the young shoots are attacked by frost and either killed or weakened in growth.

To estimate the damage thus caused the author carried out an experiment in a sugar plantation (striped cane). The methods of planting, cultivation, etc., were kept as uniform as possible and two harvests made, one on June 22, the other on August 2, 1912. The following year the cane was cut on July 24. Comparative figures of the yield and composition of the cane are given in the following table:—

Date of harvest  in 1912	Cane harvested on July 24, 1913								
	Yield in kg.		Stalks		Analysis of juice				Kg. of sugar per hectare
	per row of 100 m	per hectare	Number per row of 100 m	Average weight in kg.	Brix	Sac- charose	Glucose	purity	
June 22 . . . . .	350	23 100	519	0.76	17.6	15.8 %	0.1 %	89.6	2 290
August 2 . . . .	481	31 746	626	0.77	18.8	17.0 %	0.1 %	90.5	3 420

These results are absolutely convincing; plants cut in August, 1912 gave, in 1913, a yield per hectare exceeding that obtained with cane cut prematurely (June 22) by 8 500 kg. The injurious effect of frost is also clearly seen from the number of stalks per row of 100 m., plants cut in August 1912, yielding 107 more, in 1913, than those cut in June and, in spite of the close growth, these stalks weighed, on an average, slightly more than those cut in June. The August stalks also contained 1.2 % more saccharose and 1130 kg. more sugar per hectare.

It is quite clear that great advantage is to be derived from cutting the cane as late as possible, but, as has already been said, nearly every year the early frosts oblige the planters to harvest early. To remedy the disadvantages arising herefrom it is advised to cover stubble with soil by passing the plough between the lines. To test the benefit obtained from this method the author made an experiment in a plantation of purple sugar-cane with

alternate plots of 4 covered and 4 uncovered rows. Below are given the results obtained the following year.

	Cane harvested in 1913							
	Yield in kg.		Stalks		Analysis of juice			
	per row of 100 m	per hectare	Number per row of 100 m	Average weight in kg.	Brix	Sac- charose	Glucose	kg. of sugar per hectare
Uncovered stubble	545	35 970	700	0.79	18.8	17.0 %	0.1 %	90.5
Covered stubble.	599	39 534	719	0.83	19.3	17.8 %	0.1 %	91.9

This method is, therefore, satisfactory. The earth-covered plots yielded 3 500 kg. of cane per hectare and 650 kg. of sugar per hectare more than the uncovered plots. The method is recommended wherever practicable as it is both easy and inexpensive.

**1202 - Relation of the Density of Cell Sap to Winter Hardiness in Small Grains.** — See No. 1217 of this Review.

**1203 - Investigations into Flocculating Power in Soil.** — I. MASONI G., Coagulating Action of some Soluble Salts on Clay in Soil, in *R. Università di Pisa, Istituto di Chimica agraria, Studi e Ricerche*, Pt. 22 (1909-1914), pp. 247-293 + Bibliography of 30 Publications, Modena, 1917. II. LEONCINI, G. and MASONI, G., Determination of the Flocculating Power of Soil Solution, *Ibid.*, pp. 406-420.

SOIL PHYSICS,  
CHEMISTRY  
AND  
MICROBIOLOGY

I. An experimental study of the following three phenomena, which may be closely related : — A) flocculating power of soluble salts on clay in soil ; B) influence of this flocculation on the permeability of the soil ; C) absorption of part of the flocculating electrolytes as a result of flocculation. The study was limited to the action of certain neutral salts which are of the greatest interest from an agricultural point of view, either as essential constituents of fertilisers or because of their solution in waters which come into contact with the soil, such as chlorides, nitrates, sulphates of sodium, potassium, ammonium and calcium. Ordinary soil not too rich in clay and poor in organic matter was used. It was first dried in the air, then sifted to remove the fine particles.

**CONCLUSIONS.** — A) Chlorides have a greater flocculating power than equal weights of nitrates which, in their turn, are superior to sulphates. Calcium salts have more flocculating power than those of potassium and ammonium, and these more than sodium salts.

There is no ratio between the weight of salts used and their flocculating action. There is, however, a close relation between the solution of a given salt, the ion concentration and the degree of dissociation of the solution. The flocculating power of each salt decreases with the increase in the ion concentration, dissociation decreasing at the same time; there is no simple ratio between these phenomena. The flocculating action of the salts tested is due exclusively to the cations and the clayey matter acts as a negative

colloid. It is clear that, as the anions take no part in the flocculation the various cations act diversely.

Concentration and dissociation being equal, salts with *identical cations* and *different anions* have the same flocculating power. If only the dissociation is equal the flocculating power varies with the concentration and, if only the concentration is equal it varies with the dissociation. If both the concentration and dissociation vary, the flocculating power increases when both of these increase; it also increases when the concentration increases at the same time the dissociation decreases. There is, however, no simple ratio between the first and second ratios.

The flocculating power of salts with *identical anions* and *different cations* depends neither on dissociation nor concentration. The difference in the flocculating power of the chloride, nitrate and sulphate of the same metal does not depend on the anion, but solely on the cation, dissociation, and concentration. The *valency of the cation* has a relative influence on the flocculating power, but not the *atomic weight* of the different elements. The *relative unitary* flocculating power of each cation decreases as the concentration increases (but not in a simple ratio).

Taking the flocculating power of sodium (Na) as equal to 1, the relative unitary flocculating power of the other elements may be fixed approximately as follows:— Potassium (K), 2.4; Ammonium (NH<sub>4</sub>), 2.4; Calcium (Ca), 5.7.

B) The modifications in the permeability of the soil caused by saline solutions have no direct relation to the flocculating power of these solutions on clay, even in the case of very thick layers of soil and relatively concentrated solutions.

C) During the flocculation of the clay particles fixation of the active elements occurs, but it is not yet known if this fixation is due to the flocculation itself, i. e., to simple *adsorption*, or to an *exchange* of the elements mentioned with other elements of matters acted on by the salts.

II. — When studying the properties of soils it would be advantageous, in addition to the chemical analyses and physico-chemical investigations into the *aqueous solution*, to determine easily and rapidly the *flocculating power of this solution*. Taking as a basis the flocculation of kaolin by this solution the authors evolved the following rapid method:—

In an APPIANI levigator are placed 0.5 gm. of very fine kaolin, 200 cc. of the solution to be tested added and the whole shaken for 30 minutes and left to stand for 6 hours. The thick liquid is then poured into a flask and the amount of kaolin in suspension determined by the difference between the residue left by 100 cc. of the thick liquid evaporated to dryness at 105°C. in a platinum dish and the residue left, under the same conditions, by 100 cc. of the solution examined. The smaller the amount of kaolin in suspension, the greater should be the flocculating power of the solution examined, so that, all else being equal, it may be considered as inversely proportionate to the amount of kaolin in suspension and, in comparison with distilled water, be expressed by the formula  $Pf = \frac{A}{S}$ , where *Pf* represents the flocculating

power to be determined,  $A$  the weight of kaolin left in suspension in the distilled water, and  $S$  the weight of kaolin left in suspension in the solution examined.

**1204 - The Action of Neutral Salts on Humus and other Experiments on Soil Acidity.**

— GILLESPIE, L. J. and WISE, L. E. (Laboratories of the Office of Soil Fertility, Bureau of Plant Industry, U. S. Department of Agriculture), in the *Journal of the American Chemical Society*, Vol. XL, No. 5, pp. 796-813 + 1 Fig. Easton, Pa., May, 1918.

The investigations described deal with the action of neutral salts on humus and the behaviour of litmus paper towards different acid solutions, and were made to determine the nature of soil acidity. The addition of chlorides of sodium, potassium or barium in solution greatly increases the hydrogen-ion concentration determined electrically. As, however, this increase in acidity is also observed, though to a lesser extent, when potassium chloride acts on true solutions, saline or acid, containing no humus or other undissolved substances, great care must be taken in drawing conclusions as to the process of the phenomenon where humus is concerned. With equal concentrations barium chloride has the greatest effect on the electrometric potential of humus preparations although it has not been definitely proved that barium acts more strongly than potassium on humus.

Great care must also be taken when determining the acidity of soils with litmus paper because, even in greatly diluted solutions of hydrochloric acid, the result is largely influenced by the neutralising action of the solution analysed.

It is improbable that soils can act on litmus paper by their adsorptive power alone. The difference observed between moist soil and its aqueous extract is probably attributable to the slight solubility of the organic substances of the soil.

It is not possible at the present time to give any general explanation of soil acidity, but the determination of truly acid soils by the hydrogen electrode and suitable indicators may be considered reliable although the data on the adsorption or action of neutral salts on soils is still negative. The litmus paper test applied to moist soils may give results of a certain practical value if the necessary precautions are observed. The subsequent choice of simpler methods is connected with a deeper knowledge of the relation between the hydrogen-ion concentration, on which the true acidity of soil depends, and their various biological activities (1).

**1205 - Isolation of Cyanuric Acid from Soil, in the United States.** — L. WISE, L. E. and WALTERS, E. H. (Bureau of Plant Industry, U.S. Department of Agriculture), in the *Journal of Agricultural Research*, Vol. X, No. 2, pp. 85-91 + 1 Fig. + Bibliography of 13 Publications. Washington, July 9, 1917.

While examining a sample of Indiana silt loam the authors isolated a nitrogenous organic compound, cyanuric acid ( $C_3H_3N_3O_3$ ). It was identified by comparing in detail its properties with those of synthetic cyanuric acid, prepared by heating urea in the presence of zinc chloride (VON WALTHER'S method).

(1) See *R.*, Nov. 1917, No. 996. (Ed.).

The largest amount of this acid found was 0.150 gm. from 23 kg. of soil, but the amount was reduced by losses during evaporation. Subsequently cyanuric acid was found in various soils from different districts: — a Maine loam soil in which potatoes were grown (0.165 gm. of acid from 46 kg. of soil), in a Florida sand soil in which oranges were grown (0.04 gm. from 23 kg.), in a Texas soil (0.04 for 46 kg.) identical with that from which the authors isolated  $\alpha$ -crotonic acid (1). Cyanuric acid has apparently never previously been isolated from a natural source. It is suggested that it may be formed in soil, by the decomposition of nucleoprotein or purin bases.

1206 — **New Observations on the Biological Absorption of Methane and the Distribution of Kaserer and Söhngen Methane Organisms in Soils, Mud and Farm Manures.** — GIGLIOLI, I. and MASON, G., in *R. Università di Pisa, Istituto di Chimica agraria, Studi e Ricerche*, Pt. 22 (1909-1914), pp. 76-108. Modena, 1917.

In nature methane is produced in large quantities by the decomposition of vegetable detritus and, as it is only slightly soluble, should pass almost entirely into the atmosphere, where, as a matter of fact, only slight traces of it occur. This leads to the supposition that in soil and water it undergoes actions which change it rapidly. The investigations of M. W. BEIJERINCK and A. VAN DELDEN (1903) gave the first experimental proof of the existence of soil micro-organisms (especially *Bacillus oligocarbophilus*) capable of feeding on gaseous hydrocarbons. Later the work of H. KASERER and N. L. SÖHNGEN showed more definitely that methane really is absorbed by soil micro-organisms. From his first cultures SÖHNGEN was able to isolate a special bacillus which he called *Bacillus methanicus*.

The great interest of SÖHNGEN's experiments led the authors (1906-07) to verify them and to specify some of the conditions under which absorption of methane occurs and to collect observations on the distribution of *Bacillus methanicus* in the soils of Pisa, Italy, and its surroundings. They began their study with a few preliminary tests, followed by two sets of experiments at different seasons. In the first set (March 1-April 4, 1906) they studied the phenomenon in the presence of sewer contents and the mud of the Arno. In the second (April 30-July 30, 1907) the study was extended to field soil taken at various depths, fresh manure, rotted manure, and liquid manure, working in the light, in the dark, at a constant temperature of 30°C or average room temperature, as well as in the presence of an antiseptic (chloroform). Experiments were also undertaken to verify whether gaseous hydrocarbons other than methane could be absorbed. For all the experiments SÖHNGEN's purely mineral culture fluid was used; it contains for 100 parts of distilled water, 0.01 of calcium sulphate, 0.1 of ammonium chloride, 0.05 of magnesium-ammonium phosphate, 0.05 of bi-potassium phosphate.

RESULTS. — In the first place they confirm those of the early experiments of KASERER and SÖHNGEN, that is to say, that methane, in the presence of oxygen, is absorbed by soil bacteria. Its absorption and oxi-

(1) See *R. Jan.*, 1917, No. 6. (*Ed.*).

dation are biological phenomena which exclude the action of a soluble ferment or soil enzyme.

Light does not appear to have any special action on this biological absorption of methane which, however, is favoured by temperatures above that of the air and the surface of the soil, especially by temperatures round 30° C. Different varieties and species of methane bacteria seem to exist and act at different temperature.

In ploughed field and meadow soil, organisms which oxidise and absorb methane are rare and not very active on the surface, whereas they are abundant and active in the lower layers. They may also be in large numbers in river mud (of the Arno, for example). Manure (especially rotted and moistened), liquid manure, and sewer contents also contain many methane bacteria. Thus manure well dug in should help to enrich the soil in micro-organisms which prevent the loss of methane by forming, at its expense, new organic matter.

**CONCLUSIONS.** — Methane soil bacteria by preventing the total loss of methane of which they transform, in part at least, into new fixed organic matter either within their organisms or in their products, help to supply the soil with organic matter closely mixed with the constituents most favourable to fertility.

In appendix is given a chronological list of 82 works consulted on the origin and circulation of methane in nature and the connection of this gas with vegetable life. Some of these publications are briefly summarised.

**1207 — Experiments on the Influence on the Fertilising Power of Sewage of the Bacteria it Brings to the Soil.** — MASONI, G., in *R. Università di Pisa, Istituto di Chimica Agraria, Studi e Ricerche*, Pt. 22 (1909-1914), pp. 295-327 + Bibliography of 22 Publications; Modena, 1917.

MANURES  
AND MANURING  
ANTICRYPTO-  
GAMIC  
PRODUCTS

The aim of the experiments described was to determine whether more or less sterilised sewage exercises on the soil an influence different from that of natural sewage. In one series of experiments the sewage was spread over the earth, in another it was mixed with the earth which was placed in earthen pots containing 26 lb. In the experiments were used:—

- 1) Pots without sewage.
- 2) Pots with sewage in the natural state.
- 3) Pots with sewage sterilised by boiling.
- 4) Pots with sewage partially sterilised with sulphuric acid at the rate of 1 % of their weight.
- 5) Pots with sewage treated with an amount of sodium sulphate corresponding to 1 % of sulphuric acid.

The better to determine the action of the micro-organisms of the sewage, earth completely sterilised by heating to 130-140°C. for 8 hours was used in the following group of pots:—

- 6) Pots with sterilised soil unmixed with sewage.
- 7) Pots with sterilised soil mixed with natural sewage.
- 8) Pots with sterilised soil mixed with sewage sterilised by boiling.

In this group the sterilised soil of the pots was moistened before beginn-

ing the experiment so as to give it the same moisture content as the natural soil.

**RESULTS.** — The second set of experiments especially (sewage mixed with soil) showed the following facts with respect to the yields and condition of the plants, not including the fertilising power of the sewage itself :—

A) *Experiments with soil in the natural state.* — 1) Sterilised sewage gave much better results than natural sewage.

2) Sewage treated with 1 % of sulphuric acid gave almost the same results as sewage sterilised by boiling.

3) Sewage treated with sodium sulphate gave better results than those with natural sewage but, on the whole, slightly inferior to boiled sewage and that treated with sulphuric acid.

B) *Experiments with sterilised soil.* — Pots with natural sewage gave higher yields, not only than the control pots, but than the pots with sterilised sewage.

*Comparison between experiments A and B.* — 1) Of the control pots, those with sterilised soil always gave higher yields than those with natural soil, especially for maize.

2) With natural sewage buckwheat gave almost the same yields in both natural and sterilised soils, while maize yielded more in sterilised soil.

3) When boiled sewage was used sterilised soil was always inferior to natural soil.

**CONCLUSIONS.** — Partial or complete sterilisation tends to increase the fertilising action of sewage.

The two facts : — a) that sterilised sewage gave better results in natural than in sterilised soil ; b) that natural sewage gave better results than sterilised sewage in sterilised soil, lead to the conclusion that, although sterilised soil of itself tends to give yields equal or superior to those obtained in natural soil, an organic fertiliser free from micro-organisms has always more effect in surroundings containing micro-organisms capable of acting on it.

Other experiments, in which the earth of the pots was aerated, confirmed on the whole the above results. This calls for a continuation of the study of the influence the bacteria brought into the soil by organic fertilisers may exercise, particularly on the phenomena of nitrification and denitrification.

1208 — **Experiments on the Action of Manganese Dioxide on Nitrogenous Organic Substances, Especially Amides, With a View to the Use of this Dioxide as a Fertiliser.** — LEONCINI, G. and PIERI, C., in *R. Università di Pisa, Istituto di Chimica agraria, Studi e Ricerche*, Pt. 22 (1909-1914), pp. 328-248. Modena, 1917.

A description is given of experiments *in vitro* made to determine whether oxidation of the nitrogenous organic substances is among the many actions of which manganese dioxide is capable in soil with respect to vegetation.

**RESULTS.** — Ammoniacal compounds are in no way oxidised by manganese dioxide. On the other hand, the amides of the fatty acids and urea in

aqueous solution are easily oxidised at boiling point with the formation of nitric acid and with the same intensity in an alkaline, acid or neutral solution but, at 30°C, oxidation hardly takes place (only slight traces of ammonia are sometimes formed), except in the case of the dicyanodiamide which at this temperature also gives slight traces of nitric acid.

Amino-acids in aqueous solution are not acted on at all by manganese dioxide. They give no nitric acid at 30°C or at boiling point whether their solution be neutral, alkaline, or acid.

The amides of the amino-acids act similarly. In only one substitution derivative of an amino-acid (hippuric acid) is a tendency of part of the acid to form ammonia noticed.

Finally, uric acid and its xanthine and hypoxanthine derivatives are slightly acted on by manganese dioxide; this is seen at times only from the formation of small quantities of ammonia.

**CONCLUSIONS.** — In most of the above-mentioned compounds the nitrogen link with the rest of the molecule is so strong that it makes the molecule refractory to the oxidising action of manganese dioxide at either the relatively low temperature of 30°C, or even at boiling point, at least from a point of view of the transformation of nitrogen into nitric acid.

In the amides of the fatty acids and some of their polymers such as dicyanodiamide, the link between the amide group and the acid radical is weak, and, in several cases it suffices to boil them with an alkali or an acid to produce, by hydrolysis, the breaking up of the amide into ammonia and fatty acid. This would explain why manganese dioxide acts on such amides as a vigorous oxidiser, capable of transforming amide nitrogen into nitric nitrogen at boiling point, but to ammonia only at 30°C.

It is, then, almost certain that, apart from the small quantities of ammonia slowly transformed by the manganese dioxide, even at a temperature of 30°, if this dioxide were placed in the soil, where the temperature practically never exceeds 30°, it would have no direct oxidising effect of any practical importance on the nitrogenous organic matter. The dioxide may, however, have a very useful action by forming as a result of special environmental conditions, colloid solutions with an indirect diastatic action, by seconding the activity of bacteria, the specific agents of the various oxidations produced in soil, and, more specially, that of nitrifying bacteria.

**1209 — Analysis of Phosphatic Fertilisers.** — I. MASONI, G., Contribution to the Study of the Adulteration of Bone Superphosphates, in *R. Università di Pisa, Istituto di Chimica agraria, Studi e Ricerche*, Pt. 22 (1909-1914), pp. 139-170. Modena, 1917. — II. QUARTAROLI, A. and ROGAI, A., On the Use of Ammonium Citrate in the Determination of Phosphoric Acid. *Ibid.*, pp. 427-443.

I. — As bone superphosphates have a higher commercial value than other phosphatic fertilisers they are naturally more subject to adulteration. The author proposes a simple method to determine such adulteration which, though not general, gives useful and sometimes decisive results.

**PRELIMINARY TESTS.** — A little of the substance is carefully charred in a porcelain dish then calcined in a platinum dish which is removed now and again from the flame. Pure bone superphosphate gives off no white

steam. When, after prolonged calcination, the substance is still incandescent, pure bone superphosphate should not give a deep yellow colour which subsequently disappears, but should remain whitish or, at the most, yellowish. After cooling the calcined residue should remain white or have a paler reddish tinge. It is completely soluble in warm 10 % hydrochloric acid or, should a very small part remain undissolved, the solution should become perfectly clear after standing a little while.

**QUANTITATIVE AND QUALITATIVE TESTS.** — The moisture, total  $P_2O_5$ , water and citrate soluble  $P_2O_5$ , total  $SO_3$ , and residue insoluble in aqua regia are determined. Reducing the results to a dry matter basis at  $100^\circ C$  the values are:— $ST = \frac{\text{total } SO_3}{\text{total } P_2O_5} \times 100$  and  $SS = \frac{\text{total } P_2O_5}{\text{soluble } P_2O_5} \times 100$ .

In good bone superphosphate these values should not exceed 130 and the difference  $ST - SS$  should not be great. If the values of  $SS$  and  $ST$  are much below the minimum of 110 the purity of the product is doubtful and precipitated phosphates have probably been added. A percentage of 1.3 for the residue insoluble in aqua regia is already high.

In some doubtful cases the following *summary tests* may be useful:—see whether the aqueous solution gives a strong reaction to chlorine (precipitated phosphates); observe with a magnifying glass whether the water-insoluble residue contains carbon particles (ashes, etc.); test whether the superphosphate effervesces with acids; in special cases determine the pyrophosphoric acid (large quantities show the presence of pyrophosphates or superphosphates derived from them).

II. — The authors studies the value of determining phosphoric acid in superphosphates and basic slags by the ammonium citrate instead of the molybdate method. It was shown that, in the case of basic slag, the citrate method may sometimes lead to serious errors, although there are two sources of error which often tend to balance each other — precipitation of magnesium ferrites or citro-ferrites and incomplete precipitation of phosphoric acid. If the results disagree and the precipitates are not perfectly white and amorphous after calcination, it is possible, by estimating the iron, to determine whether errors are due to its presence. In such a case, elimination of the iron before precipitation by means of "cupferron" (ammoniacal salt of nitroso-ferri-hydroxylamine) might give reliable results. Nevertheless, this method is not generally applicable, in practice, to commercial analyses.

In the rarer cases, where iron or aluminium phosphates are concerned, the citrate method is not applicable. The principle consisting in precipitating phosphoric acid in the presence of iron or aluminium in any case or at any concentration, by preventing the precipitation of these metals by citric acid may give rise to grave errors.

The existence of the phenomena studied by the authors does not compromise the present citrate method for estimating  $P_2O_5$  in superphosphates except in a few exceptional cases of superphosphates rich in aluminium. Nevertheless these phenomena should be borne in mind in doubtful cases. The facts studied show that the choice of the concentration and quantity of solutions to be used fixed by the Italian official method is very happy, as

different amounts of ammonium citrate and n. a. g. e. s. i. m. mixture might give rise to great difficulties. The authors are, however, of opinion that, in view of the influence of its concentration on the formation of abnormal precipitates, the composition of the magnesium mixture should be more exactly fixed.

1210 - The Production and Consumption of Copper Sulphate and Copper Products in Italy (1) — FASOLATO, N. (Inspector of Industry and Work at Turin), in the *Bollettino dell'Ispettorato dell'Industria e del Lavoro*, Vol. VIII, Nos. 1-2, pp. 36-64 + 3 Diagrams. Rome, 1917.

The author's paper entitled "*Cenni sommari sugli impianti per la fabbricazione del solfato di rame esistenti nel Regno (Continente)*" (Notes on the Copper Sulphate Factories in Italy) gives information of the copper sulphate and "Caffaro paste" industry in Italy.

In the manufacture of copper sulphate refined or commercial copper is used, besides sulphuric acid, and, as accessories, electrolytic copper, scrap copper, cupriferous sand, cement copper and copper slag.

The process of manufacture may be outlined, thus:—Copper—> furnaces—> tanks for granulating the copper—> towers for treatment with sulphuric acid or other acids—> crystallisation vats—> washing and centrifugalisation of the sulphate. To produce 100 lb. of copper sulphate are required, theoretically, 25.53 lb. of pure copper and, in practice, 25.78 lb. of 99 % commercial copper.

"Caffaro paste" is a fungicide with a basis of oxychloride of copper prepared by the "Società elettrica ed elettrochimica del Caffaro" by treating copper in a special apparatus with chlorine (by-product from the SOLWAY process for the preparation of caustic soda) and transforming the copper chloride obtained into oxychloride in special mixing-mills. The present works can produce 98 400 cwt. of "Caffaro paste" containing 16.1 to 16.5 % of copper in seven months. The consumption of this paste during twelve months (from August till the end of July of the following year) was:—1913-14, 10 190 cwt.; 1914-15, 25 085 cwt.; in 1915-16, 45 080 cwt. The principal markets are Emilia, Piedmont, Venetia, Tuscany, Lombardy, the Marches, Apulia and Sicily.

In Italy there are 17 factories producing copper sulphate, including that of "Caffaro paste". During the year 1915-16 their daily output was 6 829 cwt, representing 80.5 % of the declared production capacity, 8 346 cwt. These 17 factories belong to 11 firms and are not distributed in conformity with the needs of the districts for, whereas those of Piedmont and Liguria, where 8.3 % of all the Italian vineyards is situated, supply 65 % of the total production, those of Lombardy and Venetia, where there is 20.7 % of the vineyards, produce 19.4 %, and those of central and southern Italy, where there is 71 % of the total vineyards, produce only 15.6 %.

The following table shows the trade in copper sulphate.

(1) See R., 1914, No. 108. (Ed.)

	Averages for the years 1904-1914	Year 1914-1915	Year 1915-1916
Production of Italian factories . . . . .	759 250 cwt.	807 527 cwt.	1 471 139 cwt.
Importation into Italy . . . . .	429 041	259 662	127 180
<i>Total quantity available</i> . . . . .	<b>1 288 296 cwt.</b>	<b>1 067 189 cwt.</b>	<b>1 598 319 cwt.</b>
Exportation from Italy . . . . .	26 679	5 860	112
<i>Estimated consumption in Italy</i> . . . . .	<b>1 176 610 cwt.</b>	<b>1 077 089 cwt.</b>	<b>1 607 148 cwt.</b>
Importation, in percentage of the estimated consumption . . . . .	39 %	26.5 %	8 %

It may be admitted that each year Italy consumes on an average 1 182 800 cwt. of copper sulphate, with a maximum, which is not likely to be exceeded, of approximately 1 608 000 cwt. estimated for the season 1915-16 (1).

The 17 factories already mentioned are capable of producing, in 173 working days, all the copper sulphate required for consumption in normal times and, in 234 days, the amount necessary for years of maximum consumption. Estimating that each factory can give 250 working days each year, the Italian factories should be able to produce over 1 706 000 cwt. of copper sulphate, which would be sufficient to supply the maximum consumption as well as to export about 108 000 cwt. There are probably many reasons why, in spite of the large production of the Italian factories, copper sulphate is imported from abroad, but the author holds they may all be eliminated, and it is especially important to do so because when importing copper sulphate the crystallisation water (which represents over  $\frac{1}{8}$  of the weight of the salt) is included in the payment, so that it is much more profitable to import the corresponding quantity of metallic copper.

The chief expenses in the manufacture of copper sulphate are:—cost of copper delivered to the factory (including freight, transport from Genoa to the factory, and unloading), cost of manufacture, interest and other expenses for the capital used in buying the copper, brokerage fees incurred in buying the copper, eventual rising of prices to balance the drop which may occur the following season in the price of prepared sulphate. The profit is obtained from the difference between the estimated cost of the copper sulphate and its selling price. A table of the prices of copper sulphate, illustrated by a diagram, clearly shows the greatly preponderant influence exercised on them by the cost of the metallic copper.

1211 — The Relationship between the Constituents of the Ashes of Plants Diversely Fertilised.—LEONCINI, G., in *R. Università di Pisa, Istituto di Chimica agraria, Studi e Ricerche*. Pt. 22 (1909-1914), pp. 225-245. Modena, 1917.

This paper describes preliminary investigations into the influence of certain elements and radicals added to the soil on the elements of the ashes of the plants grown in such soil. The investigations were limited to determining whether the amount of calcium and magnesium absorbed by the plant as well as their ratios, may be modified in the ash by increasing the quantity of certain elements and radicals assimilable by the plant in the soil.

Duplicate tests were made in two series of six pots each containing 10 kg. of ordinary field soil to which had been added calcium nitrate and magnesium nitrate, so that its content in these two bases should be increased. Maize was first grown, then buckwheat without further addition of fertilizer. Each series of six vases was made up as follows:—

No. 1)	Calcium nitrate + magnesium nitrate
No. 2)	» » + » » + disodium phosphate
No. 3)	» » + » » + potassium sulphate
No. 4)	» » + » » + bi-potassic phosphate
No. 5)	« « + » » + manganese sulphate
No. 6)	» » + » » + ferrous sulphate.

RESULTS. — An examination of the quantity of certain mineral constituents of the ashes shows that, under the conditions of the experiment, there would be a close relationship between the composition of the ash and the fertilizer, especially as concerns the Mg (magnesium) and  $\text{PO}_4$  (phosphoric) ions, a fact already well known. The relationship between the Mg and  $\text{PO}_4$  ions is greatly influenced by the abundance of the K (potassium) ion in the soil, and probably by a larger assimilation of potash. As the assimilation of magnesium is much influenced by the action of the potassium ion the assimilation of phosphoric acid must also be influenced, not only by the calcium and magnesium ions, but also by the potassium ion.

Under the experimental conditions, in the presence of large quantities of calcium and magnesium, cultivated plants tend to assimilate, in proportion to green matter, the same quantities of  $\text{PO}_4$  ion, whether the soil has received phosphatic fertilizer or not. If the soil has received potassic salts as well, the quantities of magnesium assimilated vary considerably. The addition of phosphoric acid compounds to the soil causes a slight decrease in the assimilation of calcium ion in proportion to the green matter of the plant.

CONCLUSIONS. — Four ions —  $\text{PO}_4$  (phosphoric), Mg (magnesium), Ca (calcium), and K (potassium) — appear to be fairly definitely connected with each other with respect to assimilation by plants. In order to decide the question the quantitative tests must be extended to a large number of elements by varying the fertilizers more rationally and comparing the variations of the assimilable element with the quantitative variations of the salts added to the soil. The author is now carrying out such experiments.

**1212 — Relation between the Total Phosphoric Acid and that of the Lecithins in Different Varieties of Peas.** — HALÁSZ, P., in the *Biochemische Zeitschrift*, Vol. I, XXXVII, Nos. 1 and 2, pp. 104-106 + 3 Tables. Berlin, 1918.

To determine the relation between the total phosphoric acid content and the phosphoric acid content of the lecithins in different varieties of a leguminous plant the author analysed the seed of different varieties of peas. He found that, in certain varieties, the lecithin content may reach 2.34 % and that the varieties most rich in lecithins are those the ripe seed of which is green, i. e., those rich in chlorophyll. These varieties contain relatively little starch. The yellow seed varieties are less rich in lecithins, but contain more starch.

There is a close relation between the total phosphoric acid content and the phosphoric acid content of the lecithins. The first is six or seven times greater than the second (six times more in peas rich in starch grains and seven times more in green peas rich in lecithins). If the total phosphoric acid content of a variety of pea be known it is, therefore, possible to determine approximately its lecithin content.

**1213 — "Sarothamnine" and "Genisteine", New Alkaloids from the Scotch Broom.**

— VALEUR A., I. On the Presence of a fixed Alkaloid in the Scotch Broom, in *Comptes Rendus de l'Académie des Sciences*, Vol. CLXVII, No. 1, pp. 26-28. Paris, July 1, 1918.

— II. On a New Volatile Alkaloid in the Scotch Broom, *Ibid.*, No. 4, pp. 163-164. Paris, July 22, 1918.

I. — Only very rarely is one alkaloid found in a plant; it might almost be said that plurality is the rule. If there are exceptions it is because one of the alkaloids is present in such a preponderating quantity that the isolation of the others presents serious difficulties. This was the case with nicotine, for long considered the only alkaloid in tobacco, until M. AMÉ PICTET showed the presence of several other alkaloids in crude commercial nicotine. The same took place with *sparteine*, extracted by STENHOUSE in 1851 from the Scotch broom (*Sarothamnus scoparius*) and which appeared to be the only alkaloid present.

The author has isolated from the two last mother-lyes obtained in successive crystallisations of *sparteine*, when they are no longer fit for obtaining the salt by concentration, two new bases, one fixed, one volatile. The first, called *sarothamnine* by the author, is considered in the present note.

The author describes the extraction method by which he obtained a white, well crystallised product by a combination of chloroform and the new alkaloid, and fine white crystals obtained by a combination of ethyl alcohol with the alkaloid.

The formula of *sarothamnine* is  $C_{15} H_{24} N_2$ , that of *sparteine* being  $C_{15} H_{26} N_2$ .

*Sarothamnine* has a remarkable facility of combining with certain solvents; it combines with methyl alcohol and with benzene, giving crystalline compounds. The author was unable to obtain the base free in the crystalline state. *Sarothamnine* acts as a monoacid to phthalein. The cold sulphuric solution clearly reduces a weak solution of potassium

permanganate; the base is, therefore, not saturated. It is an isomer of spartyrin, a base obtained by the careful oxidation of sparteine.

The author concludes: — 1) given the action of the high temperature (250° C) used in extracting sarothamnine, it is possible that the base itself does not exist in the broom, but is produced by the decomposition or transformation of an alkaloid, possibly oxygenated; 2) the formula given is provisory, as the alkaloid has not yet been completely studied.

II. — The author has isolated a fixed alkaloid, sarothamnine, from the mother-lye of the crystallisation of commercial sparteine sulphate. With an excess of soda lye, then exhaustion by ether, he was able to isolate, besides a large amount of sparteine, another volatile alkaloid, *genisteine*, a laevo-rotatory base with the formula  $C_{16}H_{28}N_2$  which, with the addition of one molecule of water, forms a hydrate which may be obtained in large crystals.

1215 — Studies on the Evolution of the Sweet Principles of Sorghum: Sugar Content at the Various Stages of Growth and the Influence of Castration. — BERTHELOT, D. and TRANNOY, R. — I. The Sugar Content of Sorghum at the Various Stages of its Growth, in *Comptes rendus des Séances de l'Académie des Sciences*, Vol. CLXVI, No. 20, pp. 824-827 + 1 Diagram; II. The Evolution of the Sweet Principles of Sorghum and the Influence of Castration, *Ibid.*, No. 22, pp. 907-910. Paris, May 21 and June 2, 1918.

This paper deals with experiments, carried out at the Plant Chemistry Station of Meudon (department of Seine-et-Oise, France), on the sugar content of sweet sorghum (*Sorghum saccharatum*) at the various stages of its development. The seeds were sown on April 25, 1917, and analyses made from lots of five plants.

The primary reducing sugars (glucose and laevulose) were the first to appear, their quantity gradually increasing until towards August 24 the total quantity of both sugars was 4 to 5 %. Saccharose, which was not present at the beginning, appeared towards August 10 and developed at first at the expense of the already existing glucose and laevulose. This is a new example of the synthesis of saccharose in the plant at the expense of the primary monoses, in agreement with the process reported long ago by BERTHELOT and BUIGNET during the ripening of oranges (1).

On October 5 the saccharose content reached 14 % and remained between 12 and 14 % during 6 weeks, a content a little below that of common sugar beets. During this period the flavour of the juice, which was at first slightly acid and astringent, became pleasant and decidedly sweet.

During the second fortnight of November the tissues began to die; the vegetable juices mingled and the hydrating diastases they contain caused hydrolysis of the saccharose, which partially returned to the state of glucose and laevulose; so that the content of these two sugars was higher at the end of vegetation.

(1) *Comptes rendus de l'Ac. des Sc.*, Vol. 51, p. 1094, 1860, (Author):

This retrogression is yet more marked in cut sorghum, i. e., in the dead plant, and is especially rapid after a frost followed by a rise in temperature, which cause the rupture of the cellular membranes. This is one way in which sorghum is inferior to beet and sugar cane. Another not less serious one is the great difficulty in crystallising sorghum juice. When small saccharose crystals were mixed with the juice evaporated to a syrupy consistency, crystallisation did not finish for several weeks; at the end of six weeks it was still incomplete.

The density increases regularly with the sugar content. If the juice contained only sugar principles in solution, the excess ( $d-1$ ) of the density over that of the water would be about proportionate to the sugar content. There is in the juice a quantity of saline principles, relatively weak as compared with the sugar principles, but sufficient to raise the density to 1.0025. The sugar content,  $s$ , from 8 % onwards at any rate, is fairly well represented by the formula  $s = 2(d - 1.0025)$ . This allows the variations in the sugar content to be controlled by an estimate of the density, i. e., by a much more simple process than a volumetric analysis with cupro-potassium solution or by a polarimetric measurement.

The suppression of the inflorescences has been recommended on the ground that it would increase the sugar content by avoiding the loss of that part of the sugar which changes to starch in the seed. The author's experiments on this subject were negative; castration did not increase the sugar content.

**CONCLUSIONS.** — It does not seem that, in normal times, sorghum can compete with the beet or sugar cane. The sweet juice of sorghum is inferior in many ways. First of all, it is difficult to crystallise, both by reason of the large proportion of so-called uncrystallisable sugars (glucose and laevulose) and the presence of gummy matter. Secondly, as soon as the plant is cut and the tissues die a large proportion of the saccharose again breaks up into glucose and laevulose; this phenomenon even occurs in the plant in the ground at the end of vegetation. Cut sorghum, is, therefore, more difficult to keep in silos than beet or cane, and treatment must not be postponed too long.

From a botanical point of view it must be noted that sorghum is reproduced annually from seed and is not so regular in growth as beet, which is biennial, or cane, which is reproduced vegetatively.

Sorghum is, however, a very hardy plant, easy to cultivate, which does well even in the north of France, and the sweet-juce, which may be extracted with presses at home, and can be used unprepared, as a syrup, would be a useful addition in the household under the present conditions caused by the war.

During experiments on bacteria and fungi the author observed the

(1) See No. 1220 of this *Review*. (Ed.).

action of tobacco smoke and methyl iodide vapour on the development of the following micro-organisms: — *Bacillus subtilis*, *B. pyocyaneus*, *B. Kiliensis*, *B. rubidus*, *B. melonis*, *B. mycoides*, *B. campestris*, *Pseudomonas radicicola*, *B. carotovorus*, *Oidium lactis*, etc. The influence on each of these is described.

It may be concluded that tobacco smoke is more or less toxic to the micro-organisms used but, in view of the very variable composition of tobacco smoke it is difficult to determine to which substance or group of substances the toxic action is due. When tobacco smoke had been passed through one or more wash bottles its toxicity is much smaller. This suggests that certain substances which can be condensed or dissolved in water take part in the toxic action.

Methyl iodide vapour causes, at first, a marked delay in development, followed by very vigorous growth, if of course, it is not sufficiently abundant to sterilise the culture medium.

**1217 — Relation of the Density of Cell Sap to Winter Hardiness in Small Grains; Investigations in the U. S. A.** — SALMON, S. C. and FLEMING, F. L., in the *Journal of Agricultural Research*, Vol. XIII, No. 10, pp. 497-506 + 1 Plate. Washington, June 3, 1918.

The death of plant tissues from cold may be due to: — 1) the formation of ice in the intracellular spaces; 2) physiological drought; 3) precipitation of the proteids; 4) desiccation of the protoplasm. In each case an increase in the electrolytic contents of the sap should increase the resistance of the plants to cold by lowering the freezing point and reducing transpiration. A close connection between the density of the sap and the resistance of the plant to low temperatures seems, therefore, probable. To study whether such a connection really exists in cereals the authors made a series of experiments with rye, wheat, emmer, barley and oats. The experiments were divided into three groups:—

*Group I.* — The sap was extracted by pressure after maceration or treatment with chloroform or toluene. A first determination, made with material collected on November 27, 1915, gave the following figures for the depression of the freezing point: —

	Freezing point
1) Rye. . . . .	— 1.044° C.
2) Durum wheat, Kharkof variety . . . . .	— 1.230° C.
3) Soft wheat, Fultz variety . . . . .	— 1.076° C.
4) Emmer ( <i>Triticum dicoccum</i> ), Black Winter variety . . . . .	— 1.012° C.
5) Barley, Tennessee Winter variety . . . . .	— 1.117° C.
6) Oats, Culberson Winter variety . . . . .	— 1.199° C.

No relation was observed between resistance to cold and sap density. It is true that the maximum depression of the freezing point is found in Kharkof wheat, which is very hardy, but Culberson oats, which are very sensitive to cold, also have a high coefficient, surpassing that of rye. These coefficients are, however, by no means constant, for in another determination made on December 17, 1915, Kharkof wheat had the lowest freezing point, —0.935°, whereas those for the other plants were: rye, —1.175°;

Fultz wheat  $-1.44^{\circ}$ ; barley  $1.320^{\circ}$ ; Winter Turf oats  $-1.260^{\circ}$ ; Culberson oats  $-1.445^{\circ}$ .

*Group II.* — Results similar to the preceding ones were obtained without extracting the sap from the plants. The leaves were wrapped round the thermometer bulb, which was then placed in the freezing mixture. Three successive determinations were made:— 1) January 16, 1917: rye,  $-3.56^{\circ}$ ; barley,  $-2.59^{\circ}$ ; 2) January 19: Kharkof wheat,  $-3.47^{\circ}$ ; rye,  $-3.58^{\circ}$ ; 3) January 27: Kharkof wheat,  $-2.17^{\circ}$ ; Fultz wheat,  $-2.06^{\circ}$ ; rye,  $-2.10^{\circ}$ . The depression of the freezing point is, therefore, greater than for extracted sap. The differences between the kinds of grain do not, however, indicate any relation between the sap concentration and resistance to cold.

*Group III.* — A study was made of the effect on the depression of the freezing point of the turgidity of the tissues which, all else being equal, has a tendency to lower the resistance of plants to cold. Wheat and oat seedlings grown in greenhouses were carefully uprooted and divided into two groups:— 1) before making the determination the seedlings were exposed to sunlight for two or three hours at room temperature, so that the leaves wilted partly; 2) the roots were immersed in water so that the leaves remained turgid. The values found for the depression of the freezing point were:—

	Lot 1 Wilted plants	Lot 2 Turgid plants
Turkey durum wheat . . . . .	$-1.945^{\circ}$	$-1.405^{\circ}$
Fultz soft wheat. . . . .	$-1.930^{\circ}$	$-1.308^{\circ}$
Winter oats. . . . .	$-2.160^{\circ}$	$-1.230^{\circ}$

The difference between the freezing point of wilted and turgid plants of the same species is much greater than that between those of different species of equal turgidity. There is, therefore, an inverse correlation between the turgidity of the tissues and concentration of the sap.

1218 — *The Action of Ultra-Violet Rays on Sugar Cane, Pineapple and Banana, in Hawaii.* — TSUJI, T., in *The Louisiana Planter and Sugar Manufacturer*, Vol. LX, No. 26, pp. 413-414 + 1 Table. New Orleans, June 29, 1918.

The author made a prolonged study of the action of ultra-violet rays on plant physiology. In the paper under review he describes his recent investigations which show perfectly clearly the connection between the action of these rays and the formation of carbohydrates, acids and other compounds in sugar cane, pineapple, banana, and other tropical plants.

**SUGAR CANE.** — Perfectly normal sugar canes were grown in the dark at a temperature of  $22^{\circ}\text{C}$ .; they grew but became pale. Thirty days later they were divided into two lots, one of which was exposed to direct sunlight, the other to ultra-violet rays from a quartz mercury vapour lamp. The etiolated leaves subjected to the action of ultra-violet rays turned a deep green after  $2\frac{1}{2}$  hours, whereas those exposed simply to sunlight kept their yellow, etiolated colour.

In another experiment three lots of sugar cane were planted. One was covered with coloured glass (to intercept 50 % of the ultra-violet rays of the sunlight), the second was exposed normally to sunlight, and the third to the combined action of the sunlight and that of the mercury vapour lamp. These three lots received equal amounts of fertiliser. After several months the second lot was found to contain 30 % more sugar than the first, and the third lot 8 % more than the second. The increase in the weight of the sugar of each lot respectively in a given time points to the possibility of reducing the 20 months normally required for each sugar harvest to less than one year by the use of ultra-violet rays.

**PINEAPPLE AND BANANA.** — Pineapples exposed to the action of ultra-violet rays ripen more rapidly than those exposed to sunlight only. Pineapples were subjected to the action of ultra-violet rays for 40 minutes each morning; the fruit was riper, more juicy and larger than that exposed to sunlight only. The same favourable action was observed on the banana. Banana leaves and stalks which had been cut and placed in water kept their original freshness even after two weeks when they had previously been subjected to the action of ultra-violet rays, whereas other untreated material was faded completely after six or seven days. The author sees in this a means of preventing the deterioration of exported bananas, but lays stress on the care necessary in the treatment as the distance, duration and intensity have to be very carefully regulated to prevent bad effects.

**PRACTICAL SOURCES OF ULTRA-VIOLET RAYS.** — The ultra-violet rays of sunlight are quickly absorbed by the atmospheric gases, and only a small proportion of them reaches the surface of the earth. The use of mercury lamps is too expensive for practical application. The author, therefore, has attempted to devise more economical methods. In his latest system the ultra-violet rays are derived from small carbon rods impregnated with sodium tungstate, uranium nitrate, ammonium molybdate and titanous chloride.

**1219 — Physical Factors of Tropism.** — DUFRÉNOY, J., in the *Revue générale des Sciences*, Year XXIX, No. 15-16, pp. 430-451. Paris, August, 1918.

The numerous investigations into tropism have shown the direction and intensity of geotropism and phototropism to depend:— 1) for a given individual, on the physical factors of the environment; 2) for given ecological conditions, on the physico-chemical properties of the cellular constituents of the individual.

Heliotropism may be modified by internal secretions and traumatic and parasitic actions affecting cellular nutrition. Lateral branches of trees which are normally horizontal may become geotropic when the top is destroyed or if attacked by parasites. For example, lateral branches of pine attacked by *Aecidium clatinum* acquire a negative geotropism, whereas branches of Scotch pine, cluster pine and spruce, borne on a level with galls of *Coccus resinifians* on the trunk, become positively geotropic.

LOEB, having observed the geotropic curve to be closely connected with the presence and position of leaves on the stalk, deducted from this the hypo-

thesis of the existence of special substances, or geotropic "hormones" that pass from the leaf to the tree, thus causing its geotropic curve.

The author considers this hypothesis neither justified nor necessary. In many completely leafless plants the floral stem curves even more rapidly than in plants with leaves. The author has made a new study of the question and his results lead him to interpret geotropic curving more simply:—

It is the result of unequal surface growth. The rate of geotropic curving and the rate of growth depend on the turgescence of the tissues and are, therefore, proportionate to the rate of absorption of water. It is for this reason that the curving and growth, rapid in stems standing in water, are slower in those standing in saline solutions and absent in plants deprived of water.

1220 - **Artificial Budding of Roots.** — MOLISCH, H., in the *Sitzungsberichte der Kaiserlichen Akademie der Wissenschaften in Wien, Mathematisch-naturwissenschaftliche Klasse, Abteilung I*, Vol. CXXVI, Pt. I, pp. 3-13 + 2 Plates. Vienna, 1917.

Although much work has been done on causing artificially the budding and growth of leaves (1) little attention has hitherto been given to this artificial budding of roots and few observations have been made on the periodical formation of roots in perennial plants (2). Moreover, the few results published do not, as a rule, agree and make it impossible to determine whether, during the winter, the roots enter a period of rest independent of outward conditions or whether they do not develop in winter as a result of unfavourable environment. If the branches of species with a marked tendency to produce adventitious roots no longer show this tendency in autumn or winter, *in spite of the presence of factors favourable to growth*, and demand some method of forcing before showing it, the hypothesis of rest independent of outward conditions, or "spontaneous" rest, would be confirmed. The author attempted to verify this by the following method: — freshly cut branches, one to three years old, of species easily producing adventitious roots (*Salix*, *Populus*, *Philadelphus coronarius*, *Viburnum Opulus*) were subjected during September, October and November to the action of substances called by the author "Treibstoffe" (substances causing budding) — hot water, tobacco and paper smoke. After treatment the branches were exposed for one or two hours in the open air, then placed in a greenhouse at a temperature of 12 to 20°C, or in a thermostat at a temperature of about 25°C.

A comparison of the branches subjected to treatment and the control branches showed that exposing the branches to tobacco smoke for 24 hours, to paper smoke for 48 hours, or to a warm water bath (at 30°C.) for 12 hours causes the leaves to fall more rapidly and the appearance, a few weeks later, of numerous adventitious roots. The control branches showed only a few small adventitious roots or none at all as may be seen from the photographs reproduced. The author concludes that there is a period during which the roots have, so to speak, no further tendency to grow; this is their period of

(1) See R. Jan., 1916, No. 62. (Ed.) — (2) See R. April, 1917, No. 313. (Ed.)

rest. This period does not, however, always depend on the presence of unfavourable factors, but is very often "independent", such as that of the budding of leaves, since, for two kinds of organs the same "activating" substance ("Treibstoffe") may shorten the period and cause budding.

**1221 - The Influence of Pollinisation and other External Factors on the Floral Organs and the Flowering Period; Research in Japan.** — MORITA, KOICHI, in *The Botanical Magazine*, Vol. XXXII, No. 375, pp. 39-52 + 6 Tables + 10 Figs. Tokyo, March, 1918.

The paper describes research work on the influence of pollinisation and other external factors (mechanical and physico-chemical) on the modification of the floral organs and the duration of the flowering period. Many tropical Orchidaceae present certain physiological phenomena which show this influence. The author chose a Japanese species — *Cymbidium virens* — which responds to the following factors by fairly strong reaction:—

1) INFLUENCE OF POLLINISATION. — This influence is felt in several ways:— the flowering period is lengthened; the stigma closes completely; the gynostemium swells; the ovary swells and lengthens.

2) INFLUENCE OF DEAD POLLEN AND POLLEN EXTRACT. — Dead pollen, killed by boiling water or chloroform, when placed on the stigma also causes it to close and the gynostemium to swell, but does not influence the duration of flowering. The author concludes that dead pollen contains active principles which are very stable with regard to heat and chloroform. For this reason he studied the influence of these extracts (small balls of cotton soaked in pollen extract obtained with hot, distilled water, placed on the stigma cavity) and found the influence to be the same as that exercised by dead pollen, except that the gynostemium does not swell.

3) INFLUENCE OF MECHANICAL FACTORS. — The placing of grains of sand on the stigma, or the artificial wounding of the gynostemium, have no effect on the flower of *Cymbidium virens*; this is contrary to the results obtained with other tropical species.

4) INFLUENCE OF THE POLLEN OF OTHER PLANTS. — Pollen from other species of the same family (Orchidaceae) has, so to speak, the same effect as pollen from the same species. On the other hand, pollen belonging to species of other families (*Prunus*, *Narcissus*, *Salix*, etc.) give absolutely negative results.

5) INFLUENCE OF CHEMICAL MATTERS. — Mineral matter has no effect; organic matter (fatty acids and certain sugars) seem to have some effect on the stigma, but the reaction has not yet been clearly demonstrated.

**1222 - Experiments on "Pneumatocarps".** — BAUMGAERTEL, O., in the *Sitzungsberichte der Kaiserlichen Akademie in Wien, Mathematisch-naturwissenschaftliche Klasse, Abteilung I*, Vol. CXXVI, Pt. I, pp. 13-40 + 4 Figs. + 1 Plate + Bibliography of 20 Publications. Vienna, 1917.

The author undertook a series of experiments on fruits which, as a result of internal gas pressure, present an abnormal growth due to the swelling of the pericarp. The author calls all fruits, of very different species, which show this inflation "pneumatocarps" ("Pneumatokarprien"), and he has studied the phenomenon from a morphological, biological and physiological point of view.

The presence of gas within the fruit may be ascertained, by pressing with the finger or pricking holes in the skin. The gases seem to be formed by the combustion of carbohydrates owing to respiration. DE NEGRI'S analytical investigations gave the following figures for the composition of these gases: —  $\text{CO}_2$ , 9.88 %; O, 16.59 %; N, 73.53 %. If these values are compared with those given for atmospheric air ( $\text{CO}_2$ , 0.04 %; O, 20.81 %; N, 79.19 %) the gas in the pericarp is seen to be much richer in  $\text{CO}_2$ . Respiration takes place in all the tissues where carbohydrates can accumulate. The author carried out a microscopical study of the tissues of "pneumatocarps" in order to determine the connection between the histological conformation of the fruits and the formation of the gases they contain. His studies on the following species:— *Astragalus Cicer* L., *Colutea halepica* Lam., *C. orientalis* Mill., *Nigella damascena* L., *Staphylea Bumalda* D. C., *S. pinnaia* L., led him to distinguish three types:—

1) *Staphylea* TYPE:—centre of respiration in the mesocarp and osmotic phenomena through the endocarp.

2) *Nigella* TYPE:—centre of respiration in the mesocarp and "setting free" ("Ablösung") of the impermeable endocarp on the one hand with formation of gas by the respiration of the embryos on the other.

3) *Leguminosae* TYPE:—centre of respiration first in the numerous embryos, then localised particularly in the meatic tissues of the placenta and funiculus, with the result that the endocarp may become the seat of respiration.

The biological importance of the internal air of "pneumatocarps" consists partly in forming a moisture-saturated environment favourable to the development of the embryos, and partly in causing the formation of fruit which is both as developed as possible and as light as possible. This is a great advantage if the action of the wind as a factor favouring reproduction be considered.

#### PLANT BREEDING

1223 - **Inheritance of the Characters of the Endosperm in Hybrids between Hard and Soft Wheats in the United States.** — FREEMAN, G. F., in *The Journal of Heredity*, Vol. IX, No. 5, pp. 211-226 + 5 Figs. Washington. May-June, 1918.

It is known that, in wheat grain with a high content of gluten as compared with that of starch, the constituents remain cemented together when the grain is completely ripe, thus giving it a compact texture and a translucent, glassy appearance. When the gluten content is not high enough to cement the mass of the endosperm completely the decreased volume of the grain is not sufficient to compensate for the loss in moisture so that air spaces occur and the grain remains soft and opaque.

The author distinguishes two types of soft grain according to the appearance and distribution of the air spaces:—

1) "true softness" type, in which the air spaces are finely scattered throughout the endosperm; it is only slightly affected by external factors.

2) "yellow berry" type, in which the air spaces occur in groups with well-defined margins; in these opaqueness may be confined to a small spot or include the whole endosperm.

The results are given of a series of experiments carried out to determine

the conditions governing the transmission of these characters. Numerous crossings were made between soft and hard wheats and the progeny analysed as far as  $F_4$ .

I. — EXPERIMENTS WITH WHEATS OF THE "TRUE SOFTNESS" TYPE. The cross hard Algerian wheat I  $\times$  Sonora 35, a soft American wheat, gave, in  $F_1$ , plants with intermediate characters, in which the maternal and paternal characters graded into each other, passing in a regular series from almost hard to almost soft wheat.

Two hybrids were chosen from  $F_1$ :— a) No. 16-1 with 23 % of hard grain and 77 % of soft and intermediate grain; b) No. 16-5, with 14 % of hard grain and 86 % of soft and intermediate grain. From each of these hybrids were sown separately:— 1) hard grain; 2) soft grain; 3) naturally mixed grain (soft, hard and intermediate). Table I shows the composition of the  $F_2$  obtained.

TABLE I. — *Composition of the  $F_2$   
of the cross hard Algerian wheat I  $\times$  Sonora 35 soft wheat.*

$F_1$ seed used for sowing		Number of $F_2$ plants with		
		all hard seed	hard, soft and inter- mediate seed	all soft seed
The hard seed {	of No. 16-1 produced in $F_2$ . . . .	12	12	1
	of No. 16-5 " " . . . .	7	7	1
The soft seed {	of No. 16-1 " " . . . .	—	14	3
	of No. 16-5 " " . . . .	4	13	5
The mixed seed {	of No. 16-1 " " . . . .	11	36	17
	of No. 16-5 " " . . . .	19	39	10
Total progeny of the cross I $\times$ 35 . . .		682	1251	336
Percentage of plants per class . . .		30 %	55 %	15 %

Although the progressive passage from one type to another makes the analysis and grading of the descendants difficult the following facts may be discerned:—

1) Selected hard seed tends to produce progeny with hard or mixed seed with a decrease or absence of completely soft seed.

2) Selected soft seeds tend to produce progeny with soft or mixed seed with a decrease or absence of completely hard seeds.

These facts become still clearer in the following generations. Thus, in 1915, a plant (No. 16-5-1-15) was isolated from the  $F_2$  of No. 16-5 which had 28 % of hard seed and 72 % of soft and intermediate seed. Table II shows the composition of the  $F_3$  obtained.

berries is small the opaque spots are small but when the percentage is high the spots are large and cover the whole endosperm.

The factors governing the appearance of yellow berry have not yet been defined or analysed. From their nature and behaviour it is, however, certain that they differ greatly from those governing "true softness" and are very sensitive to outside influence. There is no doubt that the tendency to produce yellow berries is inherited; this was proved by the experiment made from 1914-1916 with 145 pure strains of Turkey wheat. A comparison of the percentages of yellow berries in the different years of the experiments gave the following correlations:— 1914 and 1915:  $+ 57\% \pm 4\%$ ; 1915 and 1916:  $+ 33\% \pm 5\%$ ; 1914 and 1916:  $+ 41\% \pm 5\%$ . All these figures are more than six times greater than the probable error.

1224 — On a Case of Permanent Variation in the Glume Lengths of Extracted Parental Types and the Inheritance of Purple Colour in the Cross *Triticum polonicum*  $\times$  *T. Eloboni*, in England.— ST. CLAIR CAPORN, A., in the *Journal of Genetics*, Vol. VII, No. 4, pp. 259-280 + 2 Plates. Cambridge, August, 1918.

The characters of the two parents used for the cross are:—

*Triticum polonicum*:— Average glume length, 29.23 mm. Grain white, long and pointed, with a deep furrow.

*T. Eloboni*.— Average glume length, 10.58 mm. Grain short, stumpy and hard; pigmentation of the cells of the pericarp.

A) GLUME LENGTH. —  $F_1$  generation. — The glumes were intermediate in shape and size to those of the parents, but varied greatly above and below the average.

$F_2$  generation. — There were three types of glumes:— a) as long or short as those of the parents; b) almost as long or short as those of the parents; c) intermediate between those of the parents. In reconstructing the polygons of variations (1) with respect to glume length a curve with three distinct points is obtained, thus showing that segregation of the characters has taken place. According to Prof. BIFFEN (2) this curve results from the overlapping of three separate curves representing the lengths of 1) homozygous short, 2) long, 3) heterozygous short-long glumes respectively. This phenomenon is seen more clearly in  $F_3$ .

$F_3$  generation. — The seed of 183 heterozygous  $F_2$  ears were sown in separate rows. In  $F_3$  170 rows were obtained containing sufficient plants to give the following classification:—

	Number of $F_3$ lines	
	found	calculated by the ratio 1 : 2 : 1
Short glumes . . . . .	41	42.5
Short, medium and long (mixed). . . . .	87	85.0
Long glumes . . . . .	42	42.5

(1) See R. Sept, 1918, No. 973. (Ed.). — (2) BIFFEN, R. H., in the *Journal of Agricultural Science*, 1905 (Ed.).

An examination of  $F_3$  confirmed the observations made with  $F_2$ , namely, that the numbers found agree very well with those calculated and with the ratio 1 : 2 : 1 of monohybrids.

A further fact proved unmistakably is worthy of attention. In plants with long glumes, such as those of the parent *Triticum polonicum* which reappear in the  $F_2$  and  $F_3$ , the average length of the glumes (24.15 mm.) is always below that found in the parent (29.23 mm.). Similar results are probably obtained with short glumed plants, with the difference that the average length of their glumes should exceed that of the parent *Triticum Eloboni*. There is reason to believe that this shortening and lengthening of the glumes observed in the long glumed and short glumed plants of the  $F_2$  and  $F_3$  remains unchanged throughout all the generations.

B) GRAIN COLOUR. —  $F_1$  generation. — All the hybrids had the purple colour characteristic of *Triticum Eloboni*.

$F_2$  generation. — Grain with purple streaks on a light ground occurred. There were 28 plants with purple grain, 8 with streaked grain and 136 with uncoloured grain, corresponding to the ratio 3 : 1 : 12. The ratio is relatively simple, but the small number of purple-grained plants in spite of the dominance of this colour in the  $F_1$  is surprising.  $F_3$  is yet more complicated.

$F_3$  generation. — Numerous data on the colour of the grain are given and closely investigated. Nevertheless the author concludes that none of the ratios observed in the  $F_3$  can compare with the ratio 3 : 1 : 12 obtained in the  $F_2$ . None of the hypotheses put forward to explain these phenomena by multiplying the number of chromatic, inhibitory, developing factors, etc. give a satisfactory explanation and the problem of the grain colour in crosses between *Triticum polonicum* and *F. Eloboni* remains unsolved.

#### 1225 — Experiments on the Structure of Common Rice and Gluten Rice, in Japan.

— YASUKÉ, Y., in *The Botanical Magazine*, Vol. XXXII, No. 377, pp. 83-90. Tokyo, May, 1918.

By crossing common rice with gluten rice (1) an  $F_1$  was obtained composed of plants with all the external characters of common rice and an  $F_2$  with  $\frac{3}{4}$  of the plants resembling common rice and  $\frac{1}{4}$  similar to gluten rice. These facts seem to point to dominance of common rice, yet, an analysis of many  $F_2$  plants showed that the grains of the "common rice" type were not all similar but could be sub-divided into two groups:—

*Group 1.* — The endosperm of the grain is translucent and when treated with an iodine solution of potassium iodide immediately turns blue. These are characters belonging to common rice and plants of this group must be considered *homozygous* (AA).

*Group 2.* — The grains, with semi-translucent endosperms, give a red to reddish violet colour with iodine; they are intermediate between those of common rice, which are translucent, and those of gluten rice, which are opaque (BB), and should be considered *heterozygous* (AB).

The genetic data on descendants of grain which is considered hetero-

(1) Of the variety known in Cochin-China as "Nep".

zygous in respect of the above-mentioned characters, fully confirm the author's hypotheses. In six different cases the  $F_2$  showed simultaneously plants of the "common rice" and of the "gluten rice" types, in the ratio 1:2:1 observed in cases of monohybridism. The general average obtained was 1056 plants of the "common rice" type, 1740 hybrids (heterozygotes), and 884 of the "gluten rice" type. The corresponding theoretical numbers were 910, 1820, 910.

In conclusion, the above-mentioned facts seem to show that the dominance of common rice over gluten rice is incomplete, but to prove this definitely, the  $F_1$  and  $F_2$  must be analysed. This the author proposes to do.

#### 1226—The Inheritance of Tight and Loose Paleae in *Avena nuda* Crosses, in England.

— ST. CLAIR CAPORN, A., in the *Journal of Genetics*, Vol. VII, No. 4, pp 229-246 + 6 Figs. Cambridge, 1918

Results of a series of reciprocal crosses made between *Avena nuda* and three varieties of ordinary oats — Thousand Dollar, Ligowo, and Nubian Black — with the intention of studying the inheritance of the characters "tight" and "loose" paleae.

CHARACTERS OF THE PARENTS. — *Avena nuda*. — Long, dangling spikelets with as many as 9 flowers; loose, tree, membranous white and grey paleae from which the grains are easily detached.

The three following varieties have tight paleae:— Thousand Dollar Oat. — Two-grained spikelets, rarely 3- or 4-grained. Inner paleae thin but stiff, the outer thick and curled round the edges of the inner.

Ligowo Oat. — Like Thousand Dollar, save that it tends more to form 3-grained spikelets and its grain is plumper.

Nubian Black Oat. — Is a shorter strawed oat than the two previously described.

$F_1$  GENERATION. — The panicles contained a varying proportion of many-flowered spikelets of the "nuda" type, and, in the basal regions, the 2-flowered spikelets predominated.

The paleae showed every conceivable gradation from the "pure tight" of the tight grained parents to the wholly membranous palea.

The percentage of "pure tight" ranged from 20.4 to 68.7%; that of the "pure looses" from 7.8 to 46.8%. The rise of the one appears to be correlated by the fall of the other, not only when different plants are compared, but also in different zones of the same plant, as are shown in the proportions found in one plant:—

1st. node of the panicle	. . .	67.0 %	pure tight:	6.1 %	pure looses
2nd.   "   "   "   "	. . .	45.8 %	"   "	20.8 %	"   "
3rd.   "   "   "   "	. . .	26.8 %	"   "	39.0 %	"   "
4th.   "   "   "   "	. . .	5.0 %	"   "	45.0 %	"   "
Last.   "   "   "   "	. . .	7.4 %	"   "	44.4 %	"   "

This gradual diminution in the number of tight paleae and increase in the number towards the tip is a tendency noticeable in every heterozygous panicle.

In the case of Nubian Black  $\times$  *Avena nuda* the  $F_1$  colour was a bright

brown sometimes overlaid with a faint greyish flush. This may be due to the fact that the black parent is really made up of at least 3 different kinds of blacks, represented zygotically by the formulae  $BB\ B'B'\ GG$ ;  $BB\ B'B'\ gg$ ; and  $BB\ b'b'\ gg$ , where  $B$  and  $B'$  are factors for blackness, and  $G$  for grey colour.

In the  $F_1$  of the cross between *Avena nuda* and the white oats Thousand Dollar and Ligowo, the plants raised were a mixture of greys and whites, with dominance of grey in the cross grey  $\times$  white.

$F_2$  GENERATION. — This contained pure tights and mixed individuals. The proportion of plants with all grains tight were as follows:—

- 1) Out of 213 *Avena nuda* ♀  $\times$  Thousand Dollar ♂, 64 plants.
- 2) Out of 172 Ligowo ♀  $\times$  *Avena nuda* ♂, 49 plants.
- 3) Out of 133 *Avena nuda* ♀  $\times$  Ligowo ♂, 31 plants.

There were thus 518 plants with free paleae and mixed paleae, against 144 with all grains tight, in the ratio of 3 : 1, as was confirmed by further analysis.

$F_3$  GENERATION. — The plants of mixed type of the  $F_2$  gave in the  $F_3$ , the following types:—

I. — *Pure tights*. — All the grains on the plants enclosed in tough, wholly sclerotised paleae.

II. — *Tight-containers*. — One or more "pure tight" paleae, the rest varied.

III. — *Hard backs*. — No "pure tight" pales. Paleae partly membranous, partly stiffened, the hard portion varying from a slightly thickened midrib to the stiffening of nearly the whole palea.

IV. — *Penulti-looses*. — As in type III but the hardening is never found above the lowest palea in any of the spikelets. These verge closely on the

V — *Pure looses*. — All paleae absolutely membranous. These 5 types were distributed as follows in the  $F_3$ :—

$F_2$ crosses	As in $F_2$					Total $F_3$ plants
	Type I	Type II	Type III	Type IV	Type V	
Thousand Dollar ♂ $\times$ <i>Avena nuda</i> ♀ . . . . .	283	610	161	61	18	1133
<i>Avena nuda</i> ♂ $\times$ Ligowo ♀ . . . . .	163	341	113	24	16	657
Ligowo ♂ $\times$ <i>Avena nuda</i> ♀ . . . . .	164	359	95	25	12	65
Totals . . . . .	610	1310	369	110	46	2445

As might have been expected the pure tights make up almost exactly  $\frac{1}{4}$  of the total.

Type II is really a mixture of 2 distinct types; it contains some plants that never throw pure tights, as is shown on analysing the progeny. The author found that 78 out of 1310 are of Type II. On adding these 78 plants to the numbers 369 + 110 + 46 of Types III — IV — V, we get a total

of 603. In this way, the respective numbers of plants of types I, II and III — IV — V, i. e., 610 — 1232 — 603, would be in the ratio of 1 : 2 : 1, showing that *complete* tightness is determined by a single independent factor.

But what is it that causes the heterogeneity of the 603 plants of the types III — IV — V, which have the one common property of being unable to give rise to pure tights? On adding the number of plants of Types IV and V, we get 156, or about  $\frac{1}{4}$  of the total 603. This proportion shows that other factors must be coming into play, assumed by the author to be 3 in number: **X** = a factor capable of rendering *all* the paleae on the plant pure tight; **Y** = a factor capable of rendering some of the paleae on the plant pure tight; **Z** = a factor capable of rendering some of the paleae on the plant more or less sclerotised but never wholly tight.

All the pure tight forms must be homozygous to **X**, no matter whether they contain **Y** or **Z** or not. Similarly all plants which never throw pure tights must be recessive for **X** (their formula would be **xx**). On crossing these 2 types, we get a large number of  $F_1$  combinations (e. g., **XYZ x yZ**; **Xyz xyz**; **XYZ xyz**), all with a constant feature: the heterozygosity of **X**. In the  $F_2$  there is  $\frac{1}{4}$  of pure tight plants, and  $\frac{3}{4}$  of variably tightened paleae according as **Y** and **Z** are present both homozygously, both heterozygously, one homozygously and one heterozygously and so on, or both absent. It should be added that the functions assigned to the factors **Y** and **Z** are merely hypothetical.

**NUMBER OF SPIKELETS.** — Tight pales have the advantage of holding the grain and thus preventing it from being shaken out; it is thus a character of great agricultural value, which it would be desirable to combine with the many-flowered habit of the *Avena nuda* spikelets. Unfortunately the author has found that there is an absolute incompatibility between these two characters, as the food material which might be used to produce the additional grains is used up instead to strengthen the paleae.

**COLOUR OF THE PALEAE.** — There is no repulsion between grey or brown colour and pure tight paleae, though the author had previously thought there was, judging from the material studied.

1227 — Selection of a Type of "Pe-gya" Bean (*Phaseolus lunatus* var.) with a Low Prussic Acid Content, in Burma. — WARTH, F. J., and KOKOGYI, in the *Agricultural Research Institute, Pusa, Bulletin* No. 79, 11 pp. + 6 Tables. Calcutta, 1918.

The bulletin under review gives the results of a series of selection experiments aiming at the isolation of strains or types of "Pe-gya" (Burma bean, a variety of *Phaseolus lunatus*) poor in prussic acid so as to avoid, if possible, the cases of poisoning attributed to this bean by London firms.

One hundred "Pe-gya" plants were collected from the Sagaing district and the prussic acid (HCN) content of the seeds determined by the following analytical method:—

The glucoside was extracted from the finely-ground seed with alcohol. The alcoholic extract evaporated to dryness, was taken up with water, hydrolysed with dilute acid, then distilled over a water bath, air being bubbled through during the process. The hydrogen cyanide thus obtained was absorbed by 30 cc. of sodium bicarbonate solution. The distillate was then

brought up to a volume of 400 to 500 cc. with water, 30 cc. of normal potassium hydroxide and 16 cc. of an aqueous solution of ferrous sulphate added, and the whole shaken at regular intervals for three hours. The liquid was then acidified and left to stand for some days till the Prussian blue was completely precipitated. The precipitate was filtered, washed with a small amount of alkali and the Prussian blue re-precipitated. If the amount of Prussian blue was small it was determined colorimetrically, if large it was collected on a filter, ignited and weighed as ferric oxide ( $\text{Fe}_2\text{O}_3$ ).

While making these determinations large differences were noted in the prussic acid content of the seed. For selection purposes eight plants were chosen, two with a low HCN content (0.0004 to 0.0012 %), two with a high content (0.0138 to 0.0347 %) and four with a medium content (0.0018 to 0.0030, 0.0112 %).

There was no difference between the size, shape, or colour of the beans; they all consisted of a mixture of brown mottled seed with seed of a more uniform brown. No correlation could, therefore, be found between the external characters and the prussic acid content which would simplify selection by avoiding long and difficult analyses. Seed from each of these eight plants was sown in three districts with widely different climates: 1) Mandalay, in the arid zone; 2) Hmawbi, in the wet Irawaddy delta zone; 3) Tatkon, in Central Burma, where the rainfall is intermediate.

*Percentages of prussic acid in the seed of the parent plants and those of the descendants.*

Parent plants	Descendants				
	Mandalay			Hmawbi	Tatkon
	1st sowing	2nd sowing	3rd sowing		
Lot I . . . 0.0004 . . . { 1	—	—	0.0008	—	0.0010
	2	0.0008	0.0012	0.0010	0.0015
Lot II . . . 0.0012 . . . { 3	—	0.0016	0.0015	—	0.0016
	4	0.0016	0.0021	0.0017	0.0016
Lot III . . . 0.0018 . . . 5	0.0016	0.0021	0.0021	—	0.0021
Lot IV . . . 0.0022 . . . 6	0.0021	0.0027	0.0026	0.0027	0.0024
Lot V . . . 0.0030 . . . 7	0.0028	0.0043	0.0062	0.0036	0.0036
Lot VI . . . 0.0112 . . . 8	0.0058	0.0072	0.0146	0.0094	0.0043
Lot VII . . . 0.0138 . . . { 9	—	0.0249	—	—	0.0108
	10	0.0083	0.0242	0.0220	0.0101
Lot VIII . . . 0.0347 . . . { 11	—	0.0317	0.0317	—	0.0180
	12	0.0250	0.0314	0.0311	0.0188

The prussic acid content of the seed of the descendants obtained at each of these stations was determined by the method already given. The results are given in the above table together with those found for the parent plants of which lots I-II (poor in HCN) and VII-VIII (rich in HCN) had been di-

vided into two, the first with mottled seed, the second with uniformly brown seed; both these groups had been sown separately to determine whether any correlation existed between the difference in colour and the prussic acid content.

From this table it is seen that, in spite of the great differences in the climate and soil of the three stations, the seed with a low and that with a high prussic acid content always produced descendants poor or rich in prussic acid respectively.

CONCLUSIONS: — In spite of variation caused by climate and soil the prussic acid content of the "Pe-gya" bean is an inherited character which remains fairly constant in the descendants.

There is no correlation between the colour of the seed and its prussic acid content.

The best "Pe-gya" beans grown in Burma so far still contain a little prussic acid, but only half the amount found in the beans imported from Madagascar to solve the problem of decreasing this toxic principle.

**1228 - Behaviour of the Hybrids of the Two Varieties of Peas "Siroendo" and "Sans Parchemin très large Cosse"; Experiments in Japan.** — SIGEROKU, N., in *The Botanical Magazine*, Vol. XXXII, No. 377, pp. 91-102 + 2 Plgs. Tokyo, May, 1918.

The Japanese pea "Siroendo" and VILMORIN'S "Sans parchemin très large cosse" pea both have edible pods which have not the parchment-like lining common in many other varieties of peas with unedible pods. By crossing these varieties the author obtained in the  $F_1$  hybrids of a totally different character from the parents, namely with hard, parchment-like pods which did not wilt when ripe but kept their stiffness and opened when twisted.

This rather rare phenomenon suggests the presence of two complementary factors which, being separated in the parents, have no effect, but when united in the hybrid cause the parchment-like thickening of the pods.

Should this be really so plants with stiff pods and others with soft pods in the ratio 9 : 7 should be found in  $F_2$ . An analysis of 622  $F_2$  plants showed there to be 339 with hard pods and 283 with soft pods. The theoretical figures corresponding to the ratio 9 : 7 are 349.88 and 272.12 respectively. The agreement between the numbers found and those calculated is satisfactory, the deviation being  $\pm 10.88$  and the probable error  $\pm 12.37$ .

An analysis of several  $F_3$  plants showed:—

1)  $F_2$  plants with soft pods produced exclusively plants with soft pods in the  $F_3$ .

2) Of the  $F_2$  plants with hard pods only some gave in  $F_3$  descendants with hard pods (Group A), whereas the others gave a progeny of mixed plants, some having hard pods and some soft pods amongst which may be distinguished group B (with ratio of the two types equal to 9 : 7) and Group C (with ratio equal to 3 : 1). Numerous analyses showed the three groups A, B and C to be in the ratio 1 : 4 : 4 as is seen from the following data:—

Number of $F_2$ plants with hard pods	Descendants in $F_3$	
68 . . . . .	Homozygous (with hard pods) . . . . .	7 of group A
	Heterozygous . . . . .	61 { 33 of group B 28 of group C

All these facts may be accounted for if it be admitted that the thickening of the pod is due to two factors separated in each of the parents, the factor **L**, producing the parchment-like tissue but unable to exercise this action except in the presence of **D**, which acts as a developer. The results of the cross might be formulated as follows:—

$P$ (parents)	<b>LLdd + DDll</b>	
$F_1$ (1st generation of hybrids)	<b>DLLl</b>	
	<b>DDLL + 2DDLl + 2DdLL + 4DdLl</b>	(1)
$F_2$ (2nd generation of hybrids)	<b>DDll + LLdd + ddll</b>	(2)
	<b>2Ddll + 2Lddl</b>	(3)

By a study of the gametic formula of the  $F_2$  it is possible to determine in advance the composition of the  $F_3$ . The seven combinations of (2) and (3) represent individuals with a single factor which, in the following generation, will give descendants with soft (unthickened) pods. On the other hand, of the nine combinations of (1) only the first **DDLL** will give homozygous descendants composed exclusively of plants with parchment-like pods, whereas the others will produce mixed descendants in the ratio 9:7 and 3:1, as is seen from the following diagram:—

<b>DDLL</b>	with homozygous descendants
<b>DDll</b>	
<b>DdLL</b>	{ with mixed descendants in the ratio 3:1
<b>DdLl</b>	
<b>ddLL</b>	
<b>ddLl</b>	9:7

These formulae and figures agree perfectly with the data obtained by analysing  $F_2$  and  $F_3$  and confirm the author's hypothesis of the existence of two complementary factors, the fusion of which causes thickening of the pods.

1229 - **Alternate Wheats.**— DE VILMORIN, J., in *Feuille d'Informations du Ministère de l'Agriculture*, Year XXIII, No. 2, 16 pp. Paris, January 8, 1918.

"Alternate wheats" are wheats which may be sown alternately in autumn or spring as opposed to purely spring wheat, such as March chiddam, which cannot be sown in autumn. Wheats which may be considered alternate are:—

1) WHEATS WHICH BE SOWN THROUGHOUT MARCH:—

**Blé des Alliés.** — Grain sown at the end of February may ripen at the same time as winter wheat. Very fine, white grain. Does well sown in March in the north and centre of France.

**Blé seigle.** — Does well in very light soils which appear unsuited to rye.

*Amidonnier blanc*. — Suitable to cold, mountainous soils and does well where other wheats do not yield at all. Grows remarkably quickly. Yield not large.

*Blé de Noé*. — Suitable to any average good soil so long as it is healthy. Subject to rust. Does well in the south.

*Barbu à gros grain*. — Also does well in the south.

*Saumur de printemps*. — Grown in the plain of Caen.

2) WHEATS WHICH MUST BE SOWN BEFORE MARCH 15 AT THE LATEST:—

*Bordeaux*. — Does well in clay or vegetable soils as well as calcareous subsoils. Is most common in the South-West. In the West and Centre it covers half the area under wheat.

*Japhet*. — Does very well in February and often in March. Is suitable for sowing in spring where winter wheat has failed through frost. Much grown in Normandy.

*Hérisson sans barbes*. — Very resistant to heat.

3) WHEATS WHICH MAY BE SOWN IN FEBRUARY:—

*Inversible*. — Very early; adapted to the rich soils of the Centre and North. Is being grown more and more in France. Is particularly popular in Lombardy.

*Dattel*. — Is sown in February in the Pas-de-Calais and Somme departments. Ears a little late but gives a good yield regularly.

*Gros bleu*. — Does well in all soils; one of the most widely grown varieties.

*Touzelles rouge de Provence*. — Should be confined to the South as it is affected by cold. In healthy, calcareous soils in Provence and Languedoc it gives large yields.

*Rouge de Saint-Laud*. — A little sensitive to cold. Good variety for the West.

*Richelle blanche de Naples*. — For the south, and south-west districts and the calcareous soils of Berry. Slightly sensitive to cold.

*Richelle blanche hâtive*. — Excellent for the warm climates of the South and Algeria.

*Blé de Gironde*. — Beardless wheat. Tillers little but is very resistant to rust and smut. An excellent wheat for calcareous soils but very sensitive to cold.

Of the bearded wheats may be mentioned:—

*Rouge prolifique barbu*. — For the South. Adapts itself to any soil.

*Rieti*. — Gives good results in good soils and even in the medium soils of the centre.

*Pétanielle blanche de Nice*. — Variety for the South, for rich, and preferably calcareous, soils.

Finally, with certain reserve, *Bon Fermier*. — An excellent, very widely grown wheat. It is often planted in February and commonly does well in spring, but its success at this season is not absolutely assured.

1230 — **Manitoba Wheat in 1918, in Algeria.** — TRABUT, L., in *Le Progrès agricole et viticole*, Year XXXV, No. 28, pp. 38-39. Montpellier, July 14, 1918.

Manitoba wheat has given good results this year in Algeria. Its resist-

ance to rust was remarkable, not one smutty ear was found in the experimental crops of the Botanical Station, the ears were longer than in the previous year, and the grain very fine. The seed received contained several varieties which it was necessary to separate and cultivate separately. At first sight five different varieties may be easily distinguished :—

1) *Manitoba A.* — White, more or less long ears with only a few short awns at the tip and three or four abortive spikelets at the base. This form is very similar to Marquis wheat, but behaved differently in summer cultural experiments. Marquis wheat, sown on July 15, 1917, gave a crop in October; it adapted itself well to irrigation and might be cultivated with maize. Manitoba wheat, under the same conditions, grew, but only gave a few thin ears.

2) *Manitoba B.* — Is distinguished by longer ears free from abortive spikelets at the base of the ear.

3) *Fife.* — Similar ear but red; probably one of the ancestors of Manitoba.

4) *Huron.* — Long white, bearded ear.

5) *Beardless hard wheat.* — Short, close ear. This hard wheat is of good quality but can only be judged when it has been isolated and grown on a large scale under varying conditions and compared with the native wheats. At first sight it appears to be a hard wheat suitable for dry countries and late sowing. It is a spring hard wheat. It is not very common in cultivated Manitoba wheat and the ears should be sought for and cut before the harvest.

1231 — **Rhodes Grass (*Chloris Gayana*) at Cuba.** — GOODMAN, D. S. and CENTURION, M. A., in the *Revista de Agricultura, Comercio y Trabajo*, Year I, No. 1, pp. 17-18, + 1 Fig Havana, January, 1918.

Mr. Goodman, of the Chamaguey Agricultural Station, and Mr. Cunliffe of the Santiago de las Vegas Station, grew Rhodes grass experimentally. The former found it entirely satisfactory, giving a high yield, being easily made into hay and accepted by live-stock without difficulty. The latter found it suitable to poor, light soils, and one of the most productive fodder plants during the dry season (but less so during the wet season). Sowing in July in poor soil gives, in January, about 1.2 tons per acre and, eight months later 1.6 tons per acre. The hay is excellent and keeps well.

FIBRE CROPS

1232 — **Cotton Growing in Venezuela.** — HENRY, F. A., in *Commerce Reports*, No. 193, pp. 642-643. Washington, D. C., August 17, 1918.

It is stated that the cultivation of cotton has been regularly carried on in Venezuela since the American Civil War. During the last 20 years the domestic cotton-manufacturing industry has developed considerably, and in spite of an import duty of 3.43 cents per lb. on raw cotton, the industries have frequently been obliged to import it from the United States.

The chief cotton-growing regions are near Valencia and also farther in the interior in the State of Portuguesa. It is also being grown near Barquisimeto, Coro, and in other localities. The high prices that have prevailed for the past two years for cotton and cotton goods have given

a great stimulus to cotton growing. The Government has aided in this movement by the distribution of seeds. The only figures the writer has available showing the quantity raised are the following, which are stated in metric tons (of 2 204.6 lb.) transported by the "Gran Ferrocarril de Venezuela". States of Aragua and Carabobo:— 1906, 254 tons; 1912, 3 002 tons; 1915, 1 140 tons; 1916, 1 223 tons; and 1917, 1 931 tons; the production in the State of Portuguesa for 1916 was 605 tons, and in 1917, 1 944 tons. These figures probably represent seed cotton and do not by any means include the entire production of Venezuela or even of the consular district of Puerto Cabello.

Official reports predict a bright future for the industry. The locusts have proved very disastrous at times and were largely responsible for the drop in production in the Aragua-Carabobo region from 1912 to 1915. It is thought that the climate and soil of Venezuela are better suited to the growing of "Upland" varieties of cotton than "Sea Island" or "Egyptian".

**1233 - The Production of Flax in Italy.**— *Ingegneria Italiana*, Vol II, No 35, p. 103. Rome, August 22, 1918.

Flax production in Italy has been rapidly decreasing during the last twenty years as a result of the ever-increasing competition with imported cotton. Whereas the production in 1895 was 392 000 cwt. of fibre, in 1913 it was only 39 000 cwt. In that year the Italian flax industry imported 39 000 cwt. of raw flax, mostly from Russia, 3 900 cwt. of carded flax and 78 400 cwt. of flax thread, chiefly from Belgium. The Italian flax industry consists preeminently of weaving. More than three-quarters of the raw material used are imported. The most important centres of production are Lombardy, Campania, Calabria, and the Abruzzi, which together supply about 75 % of the total national production. In the five-year periods 1870-1874, 1879-1883, 1890-1894 and the three years 1911-1913, the average annual area under flax and the amount of fibre were 200 445 acres, 453 318 cwt.; 168 854 acres, 389 508 cwt.; 129 883 acres, 381 270 cwt.; and 21 698 acres and 51 334 cwt. respectively.

**1234 - Experimental Cultivation of Jute (*Corchorus olitorius*), "Malva" (*Urena lobata*) (1), and Sunn Hemp (*Crotalaria juncea*) in Cuba.**— GIRAUDIER, A, in the *Revista de Agricultura, Comercio y Trabajo*, Year I, No 1, pp. 5-7 + 5 Figs Havana, January, 1918.

The sugar industry of Cuba uses 25 million sacks annually. The author was entrusted with the task of studying the possibility of making these sacks in the country. He brought from India seed of jute (*Corchorus olitorius*), "malva" (*Urena lobata*) and Sunn hemp (*Crotalaria juncea*) which he sowed and cultivated in different parts of the island, obtaining perfectly satisfactory results. If, however, these plants are to be grown on a large scale and compete with the Hindoo production, it is essential that prepa-

(1) *Urena lobata* = "paka" or Madagascar Jute (Madagascar) (See R., Oct., 1917, No. 919) "piri-piri" (Guiana, Haiti) = "bun-vehra" (India). (Ed.)

ration of the soil and fibre be done by machinery. The author himself has invented a machine for removing the fibre.

1235 - Experiments in the Growing and Manuring of Coconuts in Ceylon. — *The Tropical Agriculturist*, Vol. L, No. 4, pp. 209-213 + 5 Tables + 2 Diagrams. Peradeniya, Ceylon, April, 1918.

The Committee of Agricultural Experiments of the Ceylon Agricultural Society publish the results of experiments in coconut growing carried out from 1915 to 1917 at Chilaw and Pitiakande. These results are summarised in the two appended tables:—

TABLE I. — *Results of experiments at Chilaw.*

Plot	No. of palms	Treatment	1915		1916		1917	
			Number of coconuts		Number of coconuts		Number of coconuts	
			per plot	per palm	per plot	per palm	per plot	per palm
1	47	Clean weeded . . . . .	1931	41.1	2677	57.0	3262	69.2
2	72	Sulphate of ammonia 2 $\frac{1}{2}$ lb. per palm, 1915. Disk harrowed monthly, 1916, 1917 . . . . .	2804	38.9	4810	66.8	5267	73.1
3	89	Groundnut cake 6 lb. per palm, 1915. Crushed fish 6 lb. per palm, 1916, 1917. . . . .	3581	40.2	5014	56.3	5217	58.6
4	81	Steamed bone meal 8 lb. per palm, 1915, 1916, 1917. . . . .	4429	54.7	5800	71.6	5648	69.7
5	84	Sulphate of potash 2 $\frac{3}{4}$ lb. per palm, 1915, 1916, 1917. . . . .	3542	42.2	5225	62.2	5690	67.7
6	78	Ammonium sulphate 4 lb. per palm, 1915, 1916, 1917 . . . . .	3829	49.0	4074	52.2	5114	65.5
7	92	Mineral mixture 6 lb. per palm, 1915, 1916, 1917 . . . . .	3304	35.9	4714	51.2	5585	60.7
8	68	Lime 10 tons per acre, 1916 1917 . . . . .	2674	39.3	3306	48.6	4057	59.6
9	85	Mixed manure 10 lb. per palm, 1915, 1916, 1917 . . . . .	3383	39.8	4499	52.9	5464	64.2
10	107	Mulched with husks in 1915, no treatment . . . . .	2933	27.4	4616	43.1	4576	42.7
11	100	Mulched with husks in rings round palm . . . . .	2861	28.6	4286	42.9	3713	37.1
12	101	Ploughed . . . . .	2936	29.1	4691	46.4	3772	37.3
13	99	Ploughed and disked, 1917. . . . .	1859	18.7	3694	37.3	3384	34.1
14	76	Dug with "mamaty" (large hoe) and mulched with leaves . . . . .	2338	18.4	2294	50.0	2054	44.6
15	81	Watered. . . . .	—	—	3087	38.1	2094	25.8
16	59	No treatment . . . . .	2373	40.2	3222	54.6	3055	51.7

NOTES. — The soil of plots Nos. 11, 12, 13 and 14 is sandy. Plot No. 15 requires more than irrigation. Mulching round the palm is insufficient unless the soil is tilled yearly and then mulched.

The results show improved yields on half the experiment plots; the most satisfactory yields were obtained on plot No. 2. Liming plot No. 8

gave satisfactory results ; it was decided to reduce the amount of lime to 10 cwt. in the future.

TABLE 11. — *Results of experiments at Pitiakande.*

11	Nitrogenous and phosphatic manure without potash . . . . .	No manure . . . . .	53	38	37	55

NOTES. — Weather conditions have a great effect. Plots 4 and 5 gave increasing yields from the beginning in spite of the weather conditions. The value of stirring the soil and of manure is clearly shown. Besides these results two tables are given, one of the yields obtained in experiments at Maha Iluppalama, the other of measurements of the development of leaves and trees made at Negombo from 1914 to 1917.

1236 — *The Properties and Botanical Origin of "Cu-nâu"*. — CHEVALIER, A., in the *Bulletin économique de l'Indochine*, Year XXI, No. 130, pp. 325-330. Hanoi-Haiphong, May-June, 1918.

The products known as "Cu-nâu" are of great commercial and industrial importance in Tonkin. The name is given to sub-spherical or oblong woody tubers varying in size from that of a fist to that of a head. They are rich in tannin and colouring matter somewhat resembling catechu and gambier or rather the dye obtained from mangroves of the genus *Cerriops*. These tubers are found in the forests of almost the whole of Tonkin and North Annam. In addition to those used for local consumption 5 000 to 8 000 metric tons are exported annually, chiefly to China.

In the Far East Cu-nâu is used exclusively for dyeing, especially for fishing nets. A cheap khaki dye, for dyeing coolies' clothes is also made from it. The tuber is soaked in water, grated, and left several days to ferment. To obtain a black colour the dyed material is buried in the bad-smelling mud at the bottom of ponds; the colour turns black but is not fast.

An analysis made by M. E. Rosé (Director of the Chemical Laboratory of the Pasteur Institute of Saigon) at the request of the Supplies Service,

gave the following results : tannins (CAFERNI method modified by SISLEY) 7.6 % of the tubers ; soluble non-tannin 5.4 % of the tubers ; insoluble non-tannin 6.8 % ; total residue taken up by water 19.8 %. The Cu-nâu tuber, therefore, contains an amount of tannin similar to that contained in the bark of oak (6.8 to 13.6 %).

The Cu-nâu tuber is collected throughout the year in the forests of the middle and high districts of Tonkin. The retail price is about \$0.40 per 30 kg. and the wholesale price about \$1 per 100 kg. In the Delta the prices have already doubled as a result of transport expenses and middlemen's fees. The quantity exported represents only a small proportion of the production, the full amount of which is unknown, as much of it evades the verifications of the forestry agents.

There are several varieties of Cu-nâu, some belonging to the genus *Dioscorea*, others to the genus *Smilax* (Liliaceae). A description is given of different varieties examined locally by the author during his forestry tours of 1917-1918 (made to draw up an inventory of the forestry resources of Indo-China) with their names in the different dialects of Indo-China. The author does not consider it advisable to make Cu-nâu plantations for root production, but it would be useful to start small plantations for producing seed with which to re-plant the Cu-nâu forests which are disappearing. The Forestry Service should make controlled forest reserves of Cu-nâu to be exploited rationally in due course.

M. PH. EBERHARDT (1) has already pointed out the use to which Cu-nâu might be put in Europe as a substitute for catechu. After showing that Cu-nâu partly loses its colouring power on drying he suggests the local preparation of a concentrated extract by infusion followed by evaporation. The author agrees that this would be the best method of utilising this product. Should it be used for tanning, as advised by M. E. ROSÉ, it would have to be exported either in dried slices or as a solid extract similar to that prepared in Borneo from mangrove bark.

RUBBER,  
GUM AND RESIN  
PLANTS.

1237 - **The Utilisation of Colonial Rubber.** — Communication from the Institut Colonial of Marseilles, presented by M. LOUIS-DOP, Delegate of France, Vice-President of the International Institute of Agriculture.

At the request of M. LEPLAE, Director General of Agriculture of the Belgian Congo, the Belgian Colonial Ministry has commissioned M. G. VAN PELT, attached to the Government of the Belgian Congo, to cooperate with the Institut Colonial of Marseilles in a study of the preparation and conditioning of rubber. After having assisted in the investigations of the Rubber Laboratory of Delft, M. VAN PELT directed the technical work of one of the largest rubber plantations of Sumatra. The Institut Colonial of Marseilles intends to study first of all the measures to be taken so that African rubber may profit by the technical progress which has been made in the preparation of rubber.

The "Cahiers Coloniaux" of October 18, 1918, published by the Institut

(1) PH. EBERHARDT, *Les matières premières végétales et animales de l'Annam*, Hanoi, 1917, p. 66. (Author)

Colonial of Marseilles, contain a report on this subject by M. VAN PELT, and another one by M. E. BAILLARD, Secretary-general of the Institut Colonial on the measures now proposed for supplying France with rubber. Extracts from the resolutions of the Office established in French Guinea to prevent fraud in exporting rubber from this country, from the Syndicate of Planters of Indo-China and the Professional Rubber Syndicate, complete this paper on the attempts made, with the active cooperation of the "Comité du Caoutchouc" of the Production Organisation Service of the Ministry of Armaments, to use colonial rubber to the best advantage.

**1238 - The Effect of Light in Healing Rubber-Tree Wounds.** — *India Rubber World*, Vol. LVII, No. 5, p. 310. New York, February, 1918.

Experiments on the effect of light on the healing of tapping wounds were recently made by HARMSEN on four year old trees of equal dimensions. From each tree a strip of bark and cambium (from 1 to 5 cm.) was removed at a height of 1.5 metres and the wound covered with blue, green, yellow, orange and colourless glass. Blue and colourless glass gave the best results, yellow the worst. Uncovered wounds healed more slowly than those covered with coloured glass, which, in their turn, healed more slowly than those covered with colourless glass.

**1239 - New Varieties of Sugar Cane Produced at Porto Rico.** — COWGILL, H. B. (Experiment Station of Río Piedras), in the *Revista de Agricultura de Puerto Rico*, Vol. I, No. 3, pp. 114-118. San Juan, 1918.

SUGAR CROPS

At Java, in the British Antilles, Barbadoes and British Guiana, new varieties of sugar are produced each year in order to obtain a cheaper product capable of competing with beet sugar. At Porto-Rico it is also necessary to eliminate the poor and degenerate varieties. Seed is selected throughout the island. The Experiment Station of Río Piedras collected as many local varieties as possible and then crossed them. The hybrids were subjected to comparative tests first at the Station itself, then in other experimental centres and by growers. This work, though still in progress, has already given excellent results.

There are four prominent new varieties — B-3412, Sealy Seedling, D-117, B-376. The first gives a large yield, its juice is of average purity and sugar content, and it is specially suited to the hills of the southern coast of the island. The same may be said of the second. The third is better suited than the others to low land, in which it produces much thicker cane. So far the fourth has been tested only at the Río Piedras Station, where it has given excellent results. Other varieties worthy of mention are B-208 for cool, rich soil, in which it surpasses the others in sugar content, but is very subject to injury from drought, D-109, B-3405, etc.

Among the varieties to be eliminated are mentioned:— Otahitú or Caña blanca of the Río Piedras district, where it yields little and is subject to disease (it grows well in the rich fields of the south coast), dura roja or Cavengerie, Yellow Bamboo, Morada, and Pinang.

The work on disease-resistant sugar cane has not yet given absolutely

immune varieties. Those which have proved most promising in the comparative experiments are : — B-4596, B-3412, D-117, Caldonia Amarilla.

**1240 — The Cultivation of Sugar-Cane in Persia.** — CALDWELL, J. L., in *Commerce Reports*, No. 129, p. 858. Washington, D. C., June 3, 1918.

It is believed that the cultivation of sugar-cane was formerly more important in the Province of Mazanderan than at present, for it appears to have been abandoned on account of the difficulty in extracting the juice. Cane is cultivated at present around the edges of cotton fields, but it could doubtless be cultivated profitably on a large scale on suitable soil. The zone of cultivation is found in the rectangle formed by the Caspian Sea and a parallel line passing Amol, Barfaruche, and Sari.

Since the beginning of the war, the price of sugar having greatly advanced, the cultivation has again been taken up. It is estimated that the 1917 harvest totaled about 120 000 Tabrizi batmans (1 560 000 pounds), of which Mazanderan consumed about half; 10 000 batmans were sent to Teheran and 50 000 batmans were transported in coasting ships to Enzeli, Chassovar, etc.

Two kinds of sugar-cane are grown in the Province :— a) The "Indi Lale" (the seeds of which are planted), which produces a sirup about the thickness of molasses of grapes, and b) "Sheker Lale" (of which the shoots are planted), yields a moist sugar which can be solidified.

Sugar-cane is planted in the spring and must be harvested in the autumn before it is cold enough for frost. The fields must be well tilled, and much moisture is necessary as in dry years good crops are not obtained.

When the crop has been cut it is stacked on the ground; near by a hut is erected for cooking the juice. Four oxen are needed for crushing the cane. The juice is boiled during the night and about 50 mans (300 pounds) of dry reeds are used as fuel in one night. The process necessitates the presence of at least four persons. When done, the sugar is poured into moulds and removed as soon as it is cold. The production is about 1 600 pounds per acre.

Before the war 12 kharvars (8 000 pounds) of moist sugar cost about 100 tomans (at normal rates of exchange 1 toman is slightly less than \$ 1) to produce and could be sold for about 120 tomans. Therefore, with such small profits, peasants could plant only around the edges of fields or in small quantities. At present the cane can be cultivated in large quantities, for while the expenses of production amount to about 120 tomans for 12 kharvars, that amount can now be sold for 240 tomans or even more. Moist sugar is worth at least twice as much as the sirup from "Indi Lale".

**1141 — Yellow Sugar Cane ("Mia-vang"), Red Cane ("Mia-ly") and Small Cane ("Mia-lau"), Varieties Grown in Indo-China.** — See 1190 of this Review.

**1142 — Future of the Yemen Coffee Trade.** — In *The Board of Trade Journal*, Vol. C, No. 1113, pp. 381-382 (380-382). London, 1918.

Coffee is the main product of Yemen agriculture and in 1909 there was a substantial increase in the value of this export as compared with the pre-

STIMULANT,  
AROMATIC,  
NARCOTIC AND  
MEDICINAL  
PLANTS

vious four years; but since the rain shortage throughout the Yemen highlands in the summer of 1910 there has been a great falling off in both quality and quantity, for many growers never emerged from the financial straits in which they were then involved. The following figures for 1909 show the normal movements of exported coffee:—

Markets.	Tons.	£.
French (chiefly Marseilles), . . . . .	1 849	112 995
United States (New York and Boston) . . . .	836	51 000
Egypt . . . . .	908	56 225
Aden (for reexport) . . . . .	372	22 750
London . . . . .	242	14 800

The various grades of Yemen coffee are named after the district of production. Harrazi coffee heads the market for quantity and general average of quality. The highest grades are Matari and Anisi, which are noted for the hardness and regularity of the beans; if stored too long at Hodeidah or elsewhere on the coast, where the air is invariably damp, the bean of both these grades is apt to whiten at the ends, which infallibly denotes deterioration to the practiced buyer; the Anisi bean is pale yellow, and very hard; it stores better than the Matari. The districts of Heimah and Reimah may be bracketed for yield and quality; the bean is somewhat irregular. Coffee from Mount Bura heads the lower grades, and is noted for the reddish tinge of the bean, which it loses if stored too long in the damp atmosphere of Hodeidah. The yield from J. Molhan is considered generally inferior to all other grades. The vague term Sherqi, or eastern, covers a large tract of country, and includes various grades; an average quality ranks in the market with the best from J. Reimah. Most of the Taizi coffee (S. Yemen) is imported via Aden. It should be noted also that the standard quality in the various districts may vary from year to year, owing to irregular harvesting, which is traceable to financial pressure on growers, or to political disturbances. Large tracts of coffee have been destroyed in disturbed areas.

1243 — **Tea in Indo-China.** — EBERHARDT, P., in the *Congrès d'Agriculture coloniale, Gouvernement Général de l'Indochine*, Hanoi Series, No. 9, 18 pp. + 1 Plate. Hanoi-Haiphong, 1918.

The species cultivated throughout Indo-China is the *Thea chinensis* Sims. (*T. sinensis* Linné), but there are many varieties. This may be explained by the variety of soils in which the crop is grown, as well as by differences in latitude and, consequently, weather conditions, which influence the development of the species (between 8° and 25° northern latitude.)

PIERRE describes five varieties of *Thea chinensis*. — *Bohea*, *viridis*, *pubescens*, *cantonensis* and *assamica*. The author (temporary Chief of the Economic Service of the General Government of Indo-China) believes there are

others, but this can only be decided by a close botanical study of cultivated and wild plants from the five parts of the Union. Samples should be collected all over Indo-China for this investigation, the result of which the author hopes to present to the Tea Congress to be held in Java in 1919.

**NATIVE CULTIVATION.** — The districts of Indo-China in which tea is most grown are, in order of importance, Tonkin, Annam and Cochinchina. Methods are very rudimentary everywhere. The greatest mistake the natives make is to plant tea in low land though the species prefers mountain districts. The slopes and table-lands of the Annam Chain, from north to south of the peninsula where the species grows wild, is admirably suited to this crop which would make all this mountain district more healthy.

The native's methods are the same everywhere. As he has not yet been persuaded to start nurseries he sows in the field, putting two or three seeds together in holes 23 to 32 inches apart. When germination is over only the strongest of the three plants is left, the other two being uprooted. Practically no care is given the plants, only weeding is practised and the great hardiness of the plant makes this sufficient. Neither pruning nor topping are carried out. Picking begins, as a rule, when the plant is three years old, and is generally so rough that the plant is entirely stripped of its leaves; this occurs several times a year.

The prices of the dried leaves vary so considerably that they cannot be attributed only to differences in the subsoil and must be due to different species or varieties.

**EUROPEAN CULTIVATION.** — Crops are so far only grown by Europeans to a small extent. There are barely 500 000 to 600 000 tea bushes in the European plantations of Tonkin and 200 000 in those of Annam. Every thing remains to be done and the Agricultural Services should appoint specialists capable of directing the development of European cultivation.

The native has not attempted to improve the cultivation of tea because, apart from the rich class who obtain their tea from China, the Annamite wishes to obtain qualities which to us are defects; he wants a very strong drink, his palate being burnt by lime and betel, and one which will enable him to shake off fatigue. Tannin, then, a glucoside, an essential oil, and an albuminoid (combined with the tannin), give the tea properties which are attenuated by industrial preparation and increase with the age of the leaf. The native picks the full-grown leaf and drinks an extract of green or simply dried tea.

**PREPARATION.** — There is only one establishment in Tonkin and two in Annam for preparing the leaves for export to France. The tea preparation industry has, therefore, yet to be created in Indo-China. This, however, can only be done when tea growing is definitely established on a rational basis and it has been possible to show the quality of Indo Chinese teas.

**WILD TEA** — Apart from the formation of plantations attention should be given to the improvement of the wild species, abundant in the mountain chain which crosses the peninsula, with a view to the production of them.

The author reported for the first time in 1907 the existence of wild tea plants in the Tamdav Range, Tonkin. He has since found this plant in

different parts of Upper Tonkin and in the whole Annam Chain (North and Central Annam). According to recent information the tea drunk by the natives of Laos is obtained exclusively from wild plants, with the exception of the tea from China consumed by the rich classes. There appear to be two species of these plants :— 1) the “ Mieng-luang ”, very common in the basins of the Nam-sang and Nam-bon (Muong of Vientiane), in the Tasseng of Natho (Vango-vieng), as well as in the Tourakhom district ; it is a forest variety but has become acclimatised well on the banks of the Honei, 2) the “ Mieng-noi ” or “ Mieng-kay ”, less common, and found almost exclusively in high districts and forests ; it grows largely in the Muong of Vang-vieng and of Borikhane, but little in the Muong of Vientiane.

TEA TRADE. — The details of the Indo-Chinese tea imports and exports are given in table form. Annam is by far the largest exporter. In 1916 Indo-China exported 918 metric tons of tea, of which 888 went to France ; 811 tons of this quantity were exported by Annam alone. In 1911 the exports were 559 metric tons (487 tons for Annam), of which 564 tons were sent to France. Indo-China imports tea from China (especially from Hong-Kong) and India. In 1915 the imports amounted to 970 metric tons, in 1916 to 903.

*Analyses of different varieties* of tea prepared by the native and by the French methods are given. The analyses were made by M. AUFRAY, Director of the Agricultural Laboratory of the Institute of Hygiene and Bacteriology at Tonkin. The teas analysed were :—

1) Teas prepared by native methods :— tea from Trâu-ninh, moc tea of 1st, 2nd, and 3rd quality, Chê-Lu, Tuyét-lu, Man-thang, Vân-trân, Chê-tuoi, Chê-tuyêt, Chê-ta, Chê-bang, Bac-quang, Chê-tu, êt Ha-giang, Tuyêt-thai, Chê-thai.

2) Tea prepared by French methods : — Chaffanjon tea.

The analyses show Tonkin teas to be poorer in tannin and alkaloid than those of Annam, which are the richest in the world in their. They could, therefore, be grown advantageously (especially the wild species) for extracting this alkaloid. The analyses also show Tonkin teas to resemble Chinese teas in their tannin and alkaloid content. They, however, differ greatly in composition, so that they should not be prepared by the methods adopted in India and China. Great attention should be given to the chemical reactions so as to find the critical point which determines their quality, especially with respect to the fermentation.

It must not be forgotten that the commercial preparation of Indo-Chinese teas is closely connected with the existence of rationally conducted plantations. Great progress has already been made in this direction. The natives supplying European firms have been persuaded to bring young leaves which resemble much more those treated in Ceylon and China, instead of old ones.

The quality of Indo-Chinese teas has been tested by experts several times. M. C. A. GUIGNON and M. DIJANNET have shown certain commercial varieties of Annam tea to be excellent. It would be easy to aromatise the tea artificially as is done by the Chinese as all the floral species they

use for this purpose are found in the colony (*Jasminum Sambac*, *Olea fragrans*, *Aglaria odorata*, lotus pollen, etc.).

All efforts should be directed to the rational and commercial production of Indo-Chinese tea. Such an enterprise should capture rapidly the French market, which hardly exceeds 1500 metric tons, and compete easily with the Ceylon and China teas at present used :—

1) by supplying a superior quality, for the excessive tannin content of Ceylon tea absolutely ruins the intestinal mucosa and its astringency injures its flavour;

2) by producing qualities equal to the best Chinese teas, with the advantage of freedom from duties and less heavy freightage.

**1244 - Vanilla as a New Product of Porto Rico.** — McCLELLAND, T. B. (Assistant Horticulturist, Mayagüez Agricultural Station), in the *Revista de Agricultura de Puerto Rico*, Vol. I, Nos. 1-2, pp. 45-48. San Juan, April-May, 1918.

Although vanilla is exported in large quantities from Guadeloupe and Saint Domingo, islands near Porto Rico, it is hardly grown at all at Porto Rico itself. Nevertheless the existence in several localities (Bayamón, Dorado, Lares, Maricao, Mayagüez, San Germán, Guánica, and Guayanilla) of wild vanilla probably belonging to species of no economic value, shows that vanilla should do very well in this country. The author made cultural experiments with vanilla at the Mayagüez Agricultural Station and obtained good results. The pods were judged excellent in appearance, scent and flavour and sold at \$ 5 per pound.

**1245 - Saffron from Kosani, Greece.** — VALDIGNÉ, in the *Journal de Pharmacie et de Chimie*, Series 7, Vol. XVIII, pp. 183-184. Paris, September 16, 1918.

Saffron grows wild in Asia Minor, Persia, and in Greece where it is cultivated most in the Kosani region, to the S. S. W. of Macedonia, on a vast plain, 2330 ft. high, and where the thermometer does not go below 5°C. The species, *Crocus sativus*, the same as that grown in France and Spain (1) is characterised by having deeply dentate stigmas; the plant barely reaches 8 in. in height and is propagated by bulbs; once planted it lasts 7 or 8 years. The flower only lasts one or two days; as soon as it appears the styles and stigmas are gathered by children and spread on carpets with a long pile where they lose  $\frac{1}{4}$  of their weight. The reddish-yellow, more or less dark coloured stigmas are separated from the bright orange yellow styles; 100 lb. of crude saffron yields 60 lb. of red saffron and 40 lb. of yellow saffron; the latter, of no commercial value, serves for domestic purposes.

The red Kosani saffron is similar to the French Gatinais saffron; it has a strong pleasant smell and gives a fine dark-red powder; owing to its fineness it is very light. The price varies according to the supply and the quality; before the war it cost about 36s. a lb., the most esteemed being that with a light red brown colour. It is mostly sent to France where it is sold as Gatinais saffron.

(1) In Italy also, especially in the province of Aquila, which gives a good-quality product. (Ed.)

1246 — Govap Tobacco and Hoemon Tobacco, the Two Best Indo-Chinese Tobaccos for Native Consumption. — See No. 1190 of this Review.

1247 — Introduction of Cinchona into Madagascar. — LEGENDRE, J. in the *Bulletin du Muséum national d'Histoire naturelle*, Year 1916, No. 7. Paris.

The Colonisation Service planted cinchonas from seed from the Dutch Indies. Certain high districts of Madagascar appear suitable to cinchona growing which, if successful, might prove a source of income for the colony.

1248 — Some Useful Plants of Chili (1). — COSTES, in the *Bulletin de la Société nationale d'Acclimation*, Year LXV, No. 4, pp. 112-115. Paris, April, 1918.

VARIOUS CROPS

A list is given of the following useful plants of Chili :—

“Algarrobo” (*Prosopis Siliquastrum* Gay = *P. juliflora* D. C.). — A tree about 20 to 25 ft. high, growing from Coquimbo to the Cachapoa river. The pods are much liked by animals. The wood is a violet-brown, very hard and used by wheelwrights; it gives very good charcoal. The seed is much appreciated medicinally for cardiac troubles on account of the tannin it contains.

“Molle” (*Lilthraea molle* Gay = *Schinus latifolius* Engl.). — A bushy tree about 16 ft. high. Before the vine was introduced a fermented drink “chicha de molle”, was made from its fruit. The white resin, obtained by making incisions in the trunk, is much used for curing leucoma and for making poultices for blows, sprains, and muscular rheumatism. The bark extract is used for nervous diseases. Wood used by wheelwrights.

“Guayacan” (*Porlieria hygrometrica* Pav. = *P. hygrometra* R. and Pav.) — A bush growing in sandy soil or alluvion. The light yellow, very hard wood is used for making small articles (combs, spoons, knife handles, bearings, etc.). The wood contains much resin which is used as an emmenagogue, stimulant, diaphoretic, and balsamic. It is recommended for herpetic troubles, chronic rheumatism, chest troubles, and as a cure for blows, bruises, and syphilitic troubles.

“Alcaparra” (*Cassia vernicosa* Clos = *C. laevigata* Willd.). — A bush common in the central provinces. The wood is very hard, resistant, and almost immune to the effects of damp and, therefore, used as props for vines. The bark and fruit are used as astringents. The leaves are purgative and the extract made from them is used to cleanse the head and free it from parasites.

“Litre”. — An evergreen bush from 16 to 20 ft. high. In the rocky mountains or those with loamy soil it is stunted and the stem grows parallel with the soil. The wood is used by wheelwrights, is very hard, and makes excellent charcoal. The “litre” is recognised as dangerous as in some people the shade, smoke, wet leaves and sap cause swellings which become pustules. Dr. A. MURILLO believes the extract could be used like thapsia to resolve eruptions; resin and volatile oil.

(1) See R., May, 1916, No. 498. (Ed.)

FRUIT GROWING 1249 — **The Pollination of Fruit in Relation to Commercial Fruit Growing** (1). — HOOPER, C. H., in *The British Bee Journal*, Vol. XLVI, No. 1463, pp. 13-14; No. 1465, pp. 28-29; No. 1467, p. 45; No. 1470, p. 73; No. 1471, pp. 79-80; No. 1473, pp. 97-98. London, 1918.

The author gives the results of his investigations and experiments on the pollination of fruit trees, including apples, pears, plums, and cherries. Lists of the fertile, and self-sterile varieties of each of these fruits are given, as well as lists of the different varieties which should be planted together. Most of the cross-pollination, specially in the case of apples, is done by insects, particularly hive and humblebees.

**APPLES.** — *Fertile*: — Irish Peach, Golden Spire, Stirling Castle, White Transparent (occasionally), Lord Derby, Tower of Glamis, Duchess of Oldenburgh, Egremont Russet, Devonshire Quarrendon, Summer Golden Pippin, Christmas Pearmain, Dominc, Washington, Ben's Red, Red Reinette, Lord Grosvenor, Early Victoria, Ecklinville, Allington, King of the Pippins, Peasgood's Nonsuch, Pott's Seedling, Gladstone, Newton Wonder.

*Self-sterile*: — Astrachan, Ribston Pippin, Lord Suffield, Hoary Morning, Warner's King, Nonpareil, Striped Beefing, Sturmer Pippin, Fearn's Pippin, Belle de Pontoise, Duchess's Favourite, Bismarck, Cox's Orange, Beauty of Bath, Hambling's Seedling, King of Tompkin's, Beauty of Kent, Cellini, Worcester Pearmain, Seaton House, The Queen, Rival, Alfriston, Lady Sudeley, Loddington, Blenheim Orange, Waltham Abbey, Prince Albert, Grenadier, Hollandbury, Lady Henneker, Cox's Pomona, Golden Noble, Annie Elizabeth, William's Favourite, Mère de Menage, Sandringham, Graham's Royal Jubilee.

*Varieties to plant together*: — Bismarck with Barnack's Beauty and Lord Derby; Warner's King and Cox's Orange; Cox's Orange Pippin with Worcester Pearmain, Duchess's Favourite, King of the Pippins and James Grieve; Beauty of Bath with Allington Pippin, Lane's Prince Albert, and Gladstone (but Gladstone does not crop well with Beauty of Bath); Bramley's Seedling with almost any variety, especially Cox's Orange, Lane's Prince Albert, Newton Wonder, and Grenadier; Lady Sudeley with Gladstone; James Grieve with Cox's Orange, Stirling Castle, King of the Pippins, and Blenheim Orange; Gladstone with Cox's Orange and Worcester Pearmain; Peasgood's Nonsuch with Wellington; Grenadier with Lane's Prince Albert and Early Victoria; Lord Derby, to some extent self-fertile, but improved by cross pollination, crops well with Graham's Royal Jubilee or Beauty of Bath; Lane's Prince Albert with Lord Derby, Stirling Castle, Grenadier, Beauty of Bath, Cox's Pomona, Bramley's Seedling and Allington Pippin; Annie Elizabeth with Warner's King; Newton Wonder with Prince Albert and Lord Derby; Worcester Pearmain with James Grieve; St. Edmund's Pippin with Ribston; Allington with Worcester Pearmain; Cox's Orange with Sturmer Pippin and Lord Grosvenor.

**PEARS.** — *Slightly self-fertile*: — (In England) Conference, Durendeu, Duchesse d'Angoulême, Colmar d'Été, Hacon's Incomparable, Marguerite Marillat; (in America) Duchesse d'Angoulême, Beurré Bosc, Beurré Diel, Doyenné d'Alençon, Flemish Beauty, White Doyenné.

*Self-sterile*: — Beurré d'Amanlis, Beurré Superfin, Catillac, Emile d'Heyst, Jargonnette, Josephine de Malines, Louise Bonne of Jersey, Beurré Alexandre Lucas; Clapp's Favourite, Williams' Bon Chrétien, Olivier de Serres, Bellissime d'Hiver, Pitmaston Duchess, General Todleben, Winter Crisanne, Marie Louise, Dr. Jules Guyot, Beurré Diel, Citron des Carmes, Uvedale's St. Germain, St. Luke, Souvenir du Congrès.

*Varieties to plant together*: — Dr. Jules Guyot with Doyenné du Comice and Williams' Bon Chrétien; Williams' Bon Chrétien with Le Lectier, Winter Crisanne and Fertility in England, with Beurré d'Anjou and White Doyenné in U. S. A., with Bailey's Bergamot in Victoria, Australia; Pitmaston Duchess with Catillac, William's Bon Chrétien, and Louise Bonne of Jersey; Doyenné du Comice crops fairly well with Pitmaston Duchess, Conference and Fertility and well with Emile d'Heyst, Souvenir du Congrès and Glou Morceau; Clapp's Favourite with Josephine de Malines; it also fruits well among a mixture of pears.

**PLUMS.** — *Self-fertile*: — Victoria and Czar fruit nearly as well self-pollinated as cross-pollinated; Denniston's Superb, Monarch (but should not be planted alone), Early Favourite, Reine Claude Violette, Myrobella, Giant Prune, Early Transparent, Reine Claude de Bavay, Prince Englebert, Early Favourite, Gisborne, Oullin's Golden Gage, Golden Transparent, Pershore, Magnum Bonum (red and white), Kentish Bush, Warwickshire Droopers, Damsons.

*Nearly self-sterile*. — Rivers' Early Prolific, Mallard, Stint.

*Self-sterile*: — Histon Gage, Early Orleans, Sultan, Kirke's Blue, Coe's Golden Drop, Coe's Violet, Washington, Late Transparent, Ickworth Imperatrice, Early Greengage, Old Greengage, Reine Claude d'Altham, Wyedale, Grand Duke, Jefferson, Pond's Seedling, Curlew, Prune d'Agen, Bryanstone.

*Varieties to plant together*: — Coe's Golden Drop with Pond's Seedling, Early Rivers, Reine Claude Violette, Rivers' Early Prolific, Prune d'Agen, Monarch, Wyedale, Denniston's Superb, Early Mirabella and Reine Claude d'Altan, does best near several varieties of plums; Early Greengage and Old Greengage do not inter-pollinate but set well with pollen of Victoria and Pond's Seedling; Wyedale with Rivers' Early Greengage and Coe's Golden Drop; July Greengage with Old Greengage and Rivers' Early Prolific; Greengage with Egg plums, Early Orleans, Monarch, Pond's Seedling, Kentish Bush, Victoria, Czar, Rivers' Early Prolific; Rivers' Early Prolific with Egg plums, Early Orleans, Czar, Monarch, Prince of Wales, Pond's Seedling; Belle de Louvain with Prince of Wales, Duke, Victoria, Czar, Egg and Early Rivers; Pond's Seedling with Pershore plums and damsons; Washington with Pond's Seedling, Early Transparent with Late Transparent and *vice versa*; Reine Claude d'Altan with Coe's Violet, Coe's Golden Drop and Jefferson; Monarch with Rivers' Early Prolific.

**CHERRIES.** — *Self-fertile*: — Morello, Kentish Wye Morello and Late Duke.

*Self-sterile*: — Black Heart, Elton, White Heart, Kentish Early Rivers, Burg d'Aunay, Black Tartarian, Bigarreau Napolcon, Bigarreau Frogmore, Early Giugne d'Annonay, May Duke.

*Varieties to plant together*: — Elton with Early Frogmore; Black Heart with Morello; Early Rivers Black with Baumann's May, Goodenston Black, Turk, Elton, Knight's Black, Governor Wood, Coronne, Florence, Black Heart, Waterloo, Black Eagle, Amber Bigarreau, Old Kentish Black and Circassian; Elton Heart with Early Rivers, Montreuse de Mezel and Frogmore; Black Tartarian or Turk with Black Eagle, Napoleon, Elton, Amber Bigarreau, Knight's Early Black and Early Rivers; Kentish or Amber Bigarreau with Black Eagle, Turk, Elton, Frogmore, Waterloo, and Governor Wood; Waterloo Black with Circassian and Amber Bigarreau; Napoleon with May Duke, Webb's Black, Governor Wood, Waterloo, Amber Bigarreau, Morello and Frogmore, in California it does well with Black Tartarian, Black Bigarreau and Bing, and in Oregon with Deacon and Lambert; Governor Wood with Elton and Napoleon; Old Kentish Black may be self-fertile but fruits well with Elton, Early Rivers, and Turk; Black Eagle with Turk; Knight's Early Black with Black Eagle; Circassian with Old Kentish Black and Early Rivers; Florence with Napoleon and Early Rivers; Roundel with Amber Bigarreau.

**GOOSEBERRIES, CURRANTS, RASPBERRIES, LOGANBERRIES, AND STRAWBERRIES.** — In England all these set and mature fruit perfectly with pollen of the same plant or variety, though some of the strawberries grown in Canada and the United States need to be interplanted with another variety for cross pollination. Insects are absolutely necessary to pollinate gooseberries and white, red, and black currants. Raspberries and loganberries give only imperfect fruit if not pollinated by insects, and strawberries, though chiefly pollinated by the movement of the air, doubtless benefit by insect pollination.

**1250—Direct Bearers at the National School of Agriculture of Montpellier (Hérault France).** — RAVAZ, L., in *Le Progrès agricole et viticole*, Year XXXV, No. 12, pp. 265-272. Montpellier, March 24, 1918.

In the School experiment field, in order to estimate with exactitude the value of each direct bearer, side by side with the new ones were placed old ones, such as Delaware, Othello, Autrichon, Canada, Secretary, Jacquez, Noah, Elvira, York-Madeira, Clinton, Herbemont, Telegraph.

**OLD HYBRIDS.** — *Delaware.* — This plant showed little resistance to mildew. Its foliage is very similar to that of *V. aestivalis*, from which it descends. The fruit is very ripe with a very pleasant flavour and would make excellent liquor. Unfortunately the smallness of the bunches excludes a high yield, nevertheless its cultivation might be attempted in districts where liqueurs are produced. It must be grafted as it is almost completely unresistant to phylloxera.

*Othello.* — Does less well than in the centre of France. Its resistance

to mildew is unsatisfactory but sufficient for the usual treatments to protect it.

*Secretary.* — No resistance to mildew.

*Jacquez.* — This was, as usual, much affected by mildew. Grafted on *Rupestris* it is exceedingly weak, but stronger ungrafted. It does not combine well with other stock, especially *V. rupestris* (suffers from thyllosis). As it is fairly resistant to phylloxera it must be planted ungrafted if the soil is of sufficiently good quality. Some of its varieties are better grafted:— *Jacquez-Marignan* (always very fine on *Rupestris*) and *Jacquez-Dauty*.

*Noah.* — Not immune to mildew, but sufficiently so and, in practice, may be grown without treatment; only in wet springs is it advisable to spray the bunches. Ungrafted it is rather weak at the School as it is subject to chlorosis and the soil is very calcarèous.

*Clinton* (Plant Pouzain or Plant des Carmes). — Resistance to mildew equal to that of *Noah* and may also do without treatment. It is less fine ungrafted than grafted and suffers especially from phylloxera.

*Elvira.* — Same remarks.

*Herbemont.* — More resistant to mildew than *Jacquez* and is easily protected by a few sprayings. Grafted on *Rupestris* it dies (effect of thyllosis). Ungrafted it suffers much from chlorosis. Is particularly affected by lime, but in clays or sandy loams containing little or no lime it grows wonderfully and resists phylloxera for a fairly long time. Wine excellent.

NEW HYBRIDS. — 71-61C. — Brother of 71-10 and fairly resistant to mildew and, to a certain extent, to phylloxera; it might be grown in soils little subject to phylloxera, or cool and deep. It is less fine grafted on *Rupestris* than ungrafted (thyllosis).

71-06 C. — Very high resistance to mildew, superior even to that of *Noah*.

71-20 — One of the best of the Bayard direct bearers. Its foliage is very healthy, so is its fruit except in cases of very violent and very early attacks of mildew. It gives a large yield, ripening at the same time as *Carrigan* and *Mourvèdre* and is, therefore, suited to the western districts of France in the soils previously occupied by *Mourvèdre*. Wine without any special taste or smell, very good to drink alone and for making good brandy. For this purpose it could be of value in *Armagnac* and *Charentes*. It can be grown ungrafted in soils little subject to phylloxera and containing little lime, or cool and deep. Does well on *Rupestris*.

1 *Seibel.* — High resistance to mildew. Very fertile though not very regular. Is not resistant to phylloxera but does well on *Rupestris*. It needs at least one early treatment and one at flowering time. The wine has a slight flavour of *Lincecumii*.

29 S. — Has too strong a musty taste; bears very well.

1020 S. — Does not appear to deserve all the good said of it; suffers from mildew, phylloxera and grafting.

128 S. — Early; does very well when grafted, but insufficiently resistant to phylloxera and must be treated several times with sulphate.

142 *E. M.* — A hybrid,  $\frac{1}{2}$  *Vinifera* and *Riparia*, obtained at the School. Its yield is small, but it is remarkably resistant to mildew.

4401. *Couderc.* — Always proves resistant to disease but its yield is irregular. It may be grown ungrafted in cool or deep soils little subject to phylloxera. Grafted on *Rupestris* it is very vigorous, even too much so, and would probably be better grafted on *Riparia*.

*Jouffreau.* — Is only an *Auxerrois-Rupestris* = *Pardes*.

28-112 *Couderc.* — Produces little and is affected by sulphur or scorching; does not do well grafted; very resistant to mildew.

580 *Jurie.* — Very resistant to mildew and almost sufficiently so to phylloxera in soils little subject to the disease. Bears well in favourable weather, sometimes non-sets. Does not require treatment.

132-11 *Couderc.* — Always fairly immune to mildew. This is one of the few hybrids which do not require sulphate spraying except under extremely unfavourable conditions. Does well ungrafted.

60 *S.* — Fine bunches; sufficiently resistant to mildew and phylloxera.

138 *S.* — Always covered with grapes which often weaken it considerably and ripen irregularly.

1025 *S.* — Valuable; fairly resistant to mildew and phylloxera. Bears well. Wine of good quality.

2007 *S.* — Appearance and almost the yield of *Aramon*. A fine neutral wine; no special flavour or smell. Hardly resists anything and does not ripen its wood in France.

9 *S.* — Very resistant to mildew but not very vigorous.

365. — Very resistant to mildew and perhaps to phylloxera as well with an almost satisfactory yield. The wine is strongly coloured and, unfortunately, has a *Rupestris* flavour.

880 *S.* — A white hybrid very valuable on account of its high resistance to mildew but which does not appear to resist phylloxera. The clusters strongly resemble those of the French vine. Fruit of no special flavour or smell and even pleasant, subject to grey rot as soon as ripe, which is both a defect and an advantage. A plant which should be kept in sight. Does very well grafted.

1000 *Seibel.* — Very resistant to mildew and perhaps sufficiently so to phylloxera in soils which are little subject to phylloxera or in vegetable mould. Ripens early with a production satisfactory for central France. Wine of a good colour, not too thick and may be drunk unadulterated. Would probably prove of value in the Rhône and Saône-et-Loire. It is subject to anthracnosis, but may be protected by washing with iron sulphate.

6239 *Castel* and 129-4 *Malègue.* — Their merits have yet to be confirmed.

157 *Gaillard.* — A heavy bearer. It is little subject to mildew though it is well to spray it once or twice with sulphate. Does not resist phylloxera. It is rather weak and should be grafted on strong stock, well cultivated and manured as its fertility has a tendency to decrease. There are

sometimes spots of scorching on the leaves, especially when grafted, but they are of no importance. Large fruit with rather a marked but agreeable flavour which recurs in the wine.

22 *Baco*. = *Maurice Baco*. — A heavy bearer, 3 or 4 clusters per branch. Foliage similar to that of *V. Labruna*, not immune to mildew though resistant to a certain extent. Grapes resembling those of *Folle*, a little acid, but neutral. Wine neutral, quite like that of *Vinifera*. Should make good brandy. Does very well on a vigorous stock.

*Oiseau-Blén* = 503 *Couderc*. — Very resistant to mildew and even to phylloxera in certain soils. Yield rather small but satisfactory where the vine is grown as an accessory. It is spreading largely on the slopes of the Ardèche because of its erect bearing and other characters. It is a vine for the farmer or metayer.

24-23 *Baco*. — Very resistant to mildew but yields very little.

The substitution of direct bearers for French vines is justified neither by the abundance nor the quality of the produce as the ordinary varieties can give more abundant and better produce than the hybrids. Nor is it always justified by a satisfactory resistance to phylloxera to assure sufficiently long duration. Only a few of the hybrids can be grown ungrafted in all soils if there is not too much lime.

In a rainy climate or cool soil, little subject to phylloxera, and in sandy and sandy-loam soils, in deep and rich land which allows the plant to heal rapidly wounds caused by insects, many of these new vines can be grown ungrafted. The lands of the South West, where the French vine held for a long time, or is still holding, without treatment, are the most favourable for direct bearers with good, or even medium, resistance to phylloxera. In a warm and dry climate direct bearers, barring the exceptions already mentioned, should be grafted on strong, vigorous stock, *Rupestris*, 1202, 93-5, 3309, 3306, etc. Only hybrids with exuberant vegetation or a tendency to non-set should be placed on *Riparia* or similar plants.

The use of these vines is justified by their resistance to disease, especially mildew. The characters of each of them from this point of view is now known. They should, therefore, be grown:—

- 1) in rainy districts, where diseases are severe: east, centre, north, west, south-west, and mountainous districts;
- 2) everywhere where the vine is cultivated as an accessory and can not be given the requisite care;
- 3) not even the best of them are suited to the production of the best wines, but in large vineyards a small place might be set apart for them for the production of wine for the workers.

In less hot and dry climates their use, for the moment at least, is very restricted, but they might be used either grafted or ungrafted, according to the soil, wherever mildew is particularly difficult to control—land frequently flooded or holding rain for a long time in hollows round the roots of plants, spongy lands impracticable for a long time after rain, where treatment is nearly always badly carried out and where mildew usually occurs every year.

4) all vines might be re-grafted using direct bearers as scions, not to avoid subsequent treatments, which would be useless, but to assure the taking of the stock in the ground. These, like French vines, are frequently destroyed by mildew in unfavourable years ; it is clear that hybrid grafts would resist much better.

There are other, more recent, hybrids, of greater promise than those studied. M. COUDERC especially has some of which great hopes are entertained. The same may be said of some of those of M. BERTILLE-SEYVE, etc.

**1251 — The Effect of Pruning on Grafted Vines (1).** — LEBRUN, L., in *Le Progrès agricole et viticole*, Year XXXV, No. 29, pp. 61-65, Montpellier, July 21, 1918.

The author (Director of the Agricultural Service of the Marne Department) gives the results and conclusions he obtained from a series of investigations in the experimental vineyard of the departmental laboratory of Châlons-sur-Marne, France, where care of the vines has been irregular since the beginning of the war.

The experimental plot, along a wall on a hillside, is exposed to the south and contains 38 to 45 % of lime very apt to cause chlorosis. The vines are Vert doré and Chardonnay grafted on 1202 and 41 B (Vert doré on 1202 is distinctly inadvisable). The method of pruning has a marked influence on the longevity of the vine and preference should be given to that in which the stock develops most. This effect is clear if it be admitted that the reserves accumulate in the old wood in larger quantities when it is of greater volume. Unfavourable years distinguished by serious attacks of mildew, lack of fertiliser and attention may follow each other with no result other than a more or less marked decrease in vegetation. This, however, is not the case when the stock is reduced, as in the Guyot pruning method, as it is much more sensitive and may disappear if neglected for one or two years. The question arises whether large trellis-work does not contribute efficiently to the resistance of the plants to phylloxera and does not suffice to explain their relative immunity.

## FORESTRY

**1252 — The Bark of Scotch Pine and Spruce.** — WRETLIND, J. E., in *Högsnärdsföreningens Tidskrift*, Year XV, No. 1, pp. 22-60 + 14 Figs. Stockholm, 1917.

This paper gives the results of a thorough study of the thickness of the bark of Scotch pine and of spruce made in forests in central Sweden.

The following conclusions were drawn from the many numerical data collected: — 1) the thickness of the bark of Scotch pine at breast height is in constant ratio with the diameter of the trunk, whatever the age of the plant ; in the spruce, on the other hand, the ratio of the bark to the diameter decreases when the diameter is larger ; 2) the bark of the spruce decreases appreciably in thickness during drying ; thus, for example, the bark of a forty year old spruce with a diameter of 22.7 cm. at breast height, dried at the temperature of an enclosed space,

(1) See R. May, 1917, No. 452. (Ed.)

decreased in thickness in 48 hours, passing from 4.4 mm. to 2.7 mm.; the decrease in the whole diameter, including the bark, was, in the same length of time, from 22.70 cm. to 22.55 cm.; apart from its commercial importance this fact calls for further investigation; 3) in the spruce, the bark is usually thicker at the base than at breast height; it decreases in thickness up to 20 or 30 % of the height of the tree, and again thickens towards the top. None of these differences are very marked, and are such that, in practice, the percentage of bark at breast height may be applied to the whole trunk.

The author recommends that, when standing wood is sold, the measurement be taken under rather than outside the bark, and that the thickness of the bark should be determined for each station. He also proposes a formula to calculate its percentage of the cubic mass.

### LIVE STOCK AND BREEDING.

1253 - **Stock-poisoning Plants of the Range, in the U. S. A.** — MARSH, C. D., in the U. S. Department of Agriculture, *Bulletin No. 575*, pp. 1-24 + 30 Plates. Washington, July 23, 1918.

HYGIENE

Very heavy losses in live stock are caused by poisonous plants. The exact extent of these losses is not known, but, in some States, it is estimated to be as much as 3 to 5 %, and in others is still higher. In Colorado such losses amount to a million dollars annually, while the annual loss of sheep in Wyoming is placed at 14.6 %. As the animals which die are mostly adult ones, ready or nearly ready for market, the loss is all the more severe. For some years past the U. S. Department of Agriculture has been making experiments with poisonous plants. Such experiments are especially difficult because many of the plants toxic to animals only cause illness when eaten in considerable quantities. The aim of the bulletin under review is to give a short description of the more important plants poisonous to stock, so that they may be easily recognised by non-technical people. The effects produced by the plant are also described as well as the time when losses usually occur together with the means of avoiding them. Special attention is drawn to the fact that most poisonous plants, with the exception of the loco (1) group, are distasteful to stock, who only eat them when there is a lack of other food. Poisoning frequently occurs when sheep are kept too long on the same bedding ground; during the first few days they eat all the available plants along the road they pass going backwards and forwards on each day, with the result that they are almost sure to consume poisonous plants later on. As far as possible sheep should be left to graze under natural conditions, that is to say, they should be able to go freely and slowly, separated from each other, and not allowed to graze over and over upon the same ground.

The plants discussed in the bulletin include: —

(1) The word "loco" is from the Spanish and means mad.

THE LOCO PLANTS (1), the most destructive of all poisonous plants. The group includes white loco, or rattle weed (*Oxytropis Lambertii*); purple loco, woolly loco, or Texas loco (*Astragalus mollissimus*); *Astragalus diphysus*. LARKSPURS (2): — *Delphinium cucullatum*, *D. Barbeyi*, *D. Menziesii*, *D. bicolor*, *D. virescens* (= *azureum*). WATER HEMLOCK (*Cicuta*) (3). DEATH CAMAS (3), *Zygadenus venenosus*, *Z. elegans*, *Z. paniculatus*. LUPINE, also known as blue pea and wild bean. LAUREL, *Menziesia glabella*, black laurel (*Leucothoe Davisiae*), *Ledum glandulosum*, white laurel (*Azalea occidentalis*), *Rhododendron albiflorum*. COMMON BRACKEN FERN (*Pteris aquilina*). WILD CHERRY. MILKWEED (*Asclepias*). WOODY ASTER (*Xylorhiza Parryi*). COLORADO RUBBER PLANT, or pingue (*Hymenoxys floribunda*). WESTERN SNEEZEWEED, or yellow weed (*Dugaldia Hoopesii*), *Psoralea tenuifolia*.

1254 — The "Enfermedad de los Rastrojos" or "Locura de los Caballos" in the Maize Growing Regions of the Argentine; Means of Control. — *El Campo*, Year II, No. 11, p. 350. Buenos Aires, 1918.

In the maize-growing regions of the Argentine and particularly in the province of Santa-Fé, a non-contagious disease of the horse appears from time to time, as in 1911 and 1918. The disease affects farm horses fed on more or less mouldy maize (whole plant or grain), or put to pasture on maize stubble. The disease is called "enfermedad de los rastrojos" (stubble disease) or "locura de los caballos" (horse madness). The mortality may attain 50 % of the farmer's stock, but decreases when the soil is begun to be cultivated for the new crop.

In some cases the disease has a very rapid course. Generally, however, it shows the following symptoms:—blindness or squinting, trembling, constipation, great excitement. In other cases it is shown by great depression and by paralysis of various parts of the body. At the post mortem examination the brain is found to be extremely softened in one or both hemispheres (usually the left).

The experts of the Veterinary Department ("Dirección general de Ganadería") of the Argentine Ministry of Agriculture, who have studied the disease very thoroughly, recommend the following treatment:—

1) If the horses are at pasture in maize fields where only the stubble remains, they must be removed at once and kept in enclosures where maize is not grown.

2) As soon as the first symptoms of the disease are seen, a hypodermic injection of pilocarpine hydrochlorate (0.2 gm.) + eserine sulphate (0.05 gm.) + distilled water (10 gm.) should be given in the neck.

3) Sometimes horses thus injected are very depressed; to stimulate them an injection must be given (and repeated 2 or 3 times a day, if necessary) composed of caffein (1 gm.) + sodium benzoate (2 gm.) + distilled water (5 gm.).

(1) See also R. Dec., 1915, No. 1309. — (2) See also R. Dec., 1915, No. 1309 and R. Jan., 1918, No. 55 — (3) See also R. Oct., 1914, No. 916, and R. Dec., 1915, No. 1309. (Ed.)

4) During the 2 or 3 days after treatment each animal must be given 2 tablespoonfulls of creoline mixed with a litre of water.

1255 - On the Isoanaphylatic Poisoning Due to Certain Immunising Serums. — CARPANO, M., in *La Clinica veterinaria*, Year XLI, No. 70, pp. 261-274. Milan, May, 1918.

The author describes the observations he has made at the "Istituto Siero - Vaccinogeno Eritreo" and at the Bacteriological Laboratory of the Army Veterinary Service at Rome, on the special hypersensibility shown by certain sick animals as regards respective and homologous immunising serums. These observations are not only of interest for the scientific study of the phenomena of immunity but also for the practical application of ordinary serotherapeutic treatment. They deal directly with streptococcal infections, cattle plague and horse sickness.

The *toxic property* of certain serums, even when normal, injected into animal species other than those from which they have been obtained, has long been known. It was thought that the toxic phenomena should be exclusively attributed to the different origin of the albumins, but it has lately been found that the phenomena may also occur, but less frequently, when albumins coming from the same species and even the animal treated are used, *i. e.*, using *isoalbumins* and *auto-albumins* respectively (PICH and YAMONOUCHI, 1908; ACHARD and TOURAINE; 1912; WIDAL, ABRAMI and BRISSAUD, 1912; PETRI, 1913; MIRICAPILLO, 1913; MEILLO, 1913; NETTER, 1915; NETTER, KOEHLIN and SALAMIER, 1916; MARIE, 1916; FINZI, 1916). The author has observed similar phenomena in the following cases:—

1) A horse that had been inoculated with a culture of streptococci and, 5 days later, with polyvalent antistreptococcal serum, showed phenomena similar to those usually occurring with anaphylactic disturbances. But in this case there was no true anaphylaxis, on account of the absence of the chief factors on which the classic form of the phenomenon is based, *i. e.*:—  
a) heterogeneous serum; b) the existence of a preceding action leading to the phenomenon. In addition, the phenomenon of antianaphylaxis or de-anaphylaxis, which renders the organism insensitive after a first anaphylactic crisis, did not show itself.

2) In cattle injected in the jugular with 80-100 cc. of homologous anti-plague serum, the author has frequently found that the grave poisonings often followed by sudden death were not due to the phenol contained in the serum (cattle tolerate up to 2 gm. injected intravenously with impunity), nor to the traumatic action of the albumin flakes suspended in the serum, nor to air bubbles introduced into the veins. As a result of this the author abolished the intravenous method and has limited the treatment of cattle plague solely to subcutaneous serotherapy which, when given when the disease first shows itself, gives a high percentage of recoveries.

3) In horses suffering from horse-sickness and treated with a homologous serum, particularly when injected directly into the jugular. This serum has a powerful haemolytic action. THEILER made similar observations in 1904, during his researches on immunisation against horse-sickness in South Africa.

Given that, in all the previous cases, a homologous serum (*i. e.*, obtained from the same species of animal) was used, it must be admitted, contrary to the still current opinion, that the serum of certain organisms, whether specially treated or not, can possess the properties of antigens towards organisms belonging to the same species; in other words an *individual specificity*, whether acquired or natural, must be admitted. Those cases of hypersensibility observed in some of the animals treated are much more pronounced and frequent when the serums used are obtained from material hyperimmunised with animal products (virulent blood), as is the case with cattle plague and horse-sickness, than when they are obtained, on the contrary, from animals hyperimmunised with bacterial material, as is the case in streptococcal infection. The author gives this hypersensibility the name of "*tossicose anafilatoïde*" (anaphylactoid poisoning), thus indicating those reactions that are special to the organism, similar to the anaphylactic manifestations that occur in the organism itself as the result of the introduction of normal or immunised homologous serums, without there being a previous sensitisation (1).

The author discusses some of the hypotheses put forward to explain the origin of the phenomena in question: — above all, individual predisposition; presence of incompletely neutralised antigens in the serums; eventual reaction between the antigens contained in the sick organism and the antibodies introduced with the immuniser; presence of isoagglutinins, isoprecipitins and isolysins in the immuniser; complex modifications of a bio-physical-chemical nature undergone by the serums during their preparation, and which would give them antigenic or completely toxic properties.

**PRACTICAL CONCLUSIONS.** — In some infections, a certain number of sick individuals (consisting of predisposed subjects) can show a particular hypersensibility as regards homologous preventive immunisers, especially when they are introduced directly and in considerable quantities into the circulation; this is why intravenous serotherapy when it is the case of certain serums and in spite of their efficacy, is not free from disadvantages which, from simple, passing disturbances, may develop to the most alarming morbid symptoms and even cause the death of the subject.

**1256 — The Anaphylactic Nature of Parasitic Poisoning.** — VAN ES, L. and SCHEALCK, A. F. (Veterinary Department of the North Dakota Agricultural Station), in the *Annales de l'Institut Pasteur*, Year XXXII, No. 7, pp. 310-362 + 5 Tables + 5 Figs. + Bibliography of 20 Publications. Paris, 1918.

The part played by the filtrable, ultra-microscopic virus of VALLÉE and CARRÉ in infectious anaemia of the horse has been confirmed by many researches. Again, the recent explanations of the etiology of the disease proposed by MM. SEYDERHEHN (Strasbourg) during their researches on the pathological nature and treatment of infectious anaemia of the horse have

(1) BEHRING calls *anaphylactoid substances* those that reproduce the syndrome of anaphylaxia without there being a previous preparatory action. See PESCI, *Forme anafilattiche*, Turin, 1916. (Author)

greatly interested other workers. The results arrived at by the authors are given below.

Anaemia of the horse can be produced artificially, down to every detail, by injecting aqueous extracts of *Gastrophilus equi* and *G. haemorrhoidalis* (*Oestrus*).

Judging from its action and its behaviour as regards physical and chemical influences, the active constituent is an animal poison, called *oestrine* by the authors.

The toxic action of oestrine, exclusively specific for the horse (and ass), is reabsorbed by the gastro-intestinal canal; it occurs in the excreta of the larvae of *Gastrophilus* and that of the species *haemorrhoidalis* is much more toxic than that of the species *equi*.

Pernicious anaemia produced artificially in this way can be transmitted to healthy horses by means of the blood, and by the blood of the latter to other horses; in nature pernicious anaemia is not produced by an ultra-visible virus, but by oestrine alone.

The authors have checked their theory by a number of experiments:—

1) Study of the results produced by injecting the horse with extracts of the larvae of *Gastrophilus* (intravenous and subcutaneous injections; action of dialysis, alcoholic and acetone extracts and heat on the poison of *Oestrus*); 2) study of oestrine as regards its importance in the pathogenesis of the disease and on the eventually anaphylactic character of the reaction produced by the injections. In this way the authors have been able to formulate the following theory:—

There is no reason to believe that the species of *Gastrophilus* play a *specific part* in the etiology of pernicious anaemia of the horse; the severe poisoning following the injection of gastrophilic matter observed by MM. SEYDERHEHN and also by the authors, is not caused by a specific substance such as oestrine; it is simply the *manifestation of anaphylaxia* and is quite analogous to that produced by proteins. Many parasites sensitise their hosts which, after injection or instillation, give anaphylactic or allergic reactions. The more or less constant presence of the parasites in certain parts of the host's body makes the idea very plausible that the host is constantly charged with anaphylatoxins and it is quite possible that such a poisoning might lead to morbid conditions.

This hypothesis of a *parasitic anaphylaxia* raises many questions and opens a wide field to the investigator, such as:— the study of the consequences of anaphylactic poisoning and its relations with certain chronic diseases; practical application to the diagnosis of certain diseases; the study *in vitro* of anaphylactic sensitisation of parasitic origin, etc.

1257—Some Biological and Control Studies of *Gastrophilus haemorrhoidalis* and Other Bots of Horses, in the Dakotas and Montana, U. S. (1)—DOVE, W. E., in U. S. Department of Agriculture, Bulletin No. 597, 51 pp. + 4 Fig. + 5 Plates + Bibliography of 38 publications. Washington, April 9, 1918.

Three species of horse bots—the common bot-fly (*Gastrophilus in-*

(1) See also R. May, 1917, No. 458. (Ed.)

*testinalis*), the throat bot-fly (*G. nasalis*), and the nose fly (*G. haemorrhoidalis*) — occur in the United States, and each is a source of considerable injury to horses. This injury is produced through irritation caused by the flies at the time the eggs are laid and by the attachment of the larvae, or bots, in the alimentary tract.

*Gastrophilus intestinalis* and *G. nasalis* are widely distributed in the United States, but *G. haemorrhoidalis* is confined to the North-Central and northern Rocky Mountain States.

The nose fly (*G. haemorrhoidalis*) is by far the most annoying to horses at the times its eggs are laid. The adults appear early in June and reach the maximum of abundance during the first half of the season, disappearing with killing frosts. The eggs are deposited on the minute hairs on the lips, and those near the edges which are kept moist and receive friction hatch in from 5 to 10 days. The larvae are taken in with food or water and attach themselves to the walls of the stomach. Here they remain until the following winter or spring and then migrate to the rectum, where they reattach. Before leaving the host they usually attach close to the anus and protrude from it. They remain in this position from 40 to 70 hours. After dropping to the ground the bots seek protection and pupate in from 18 to 170 hours later. The pupal stage lasts from 21 to 68 days. The adults are very active and as they deposit only one egg at a time they are not so frequently seen about horses as are the adults of the common bot-fly. They take no food in the adult stage. Their length of life is from 1 to 7 days.

The throat bot-fly (*G. nasalis*) deposits its eggs on the hairs under the jaws and to some extent on the shoulders and other parts of the host. The larvae of this species attach themselves to the walls of the pharynx and also to those of the stomach and duodenum. They do not reattach in the rectum or at the anus as do the bots of the nose fly. Pupation occurs in from 1  $\frac{1}{2}$  to 2 days after the larvae have passed from the host, and adults emerge in from 20 to 56 days later. The adults are somewhat longer lived than those of the nose fly. The flies cause considerable annoyance to horses during oviposition but not as serious as in the case of the nose fly.

The common bot-fly (*G. intestinalis*) usually appears later in the season than the nose fly and becomes most abundant just before killing frosts. The eggs are deposited on all parts of the body but preferably on the fore legs. They hatch upon the application of moisture and friction. From 9 to 11 days after oviposition appears to be the most favourable period for hatching, although some may hatch as early as 7 days and others as late as 96 days after oviposition. The larvae attach in any part of the stomach but the last-stage bots are found mostly in the left sac. They continue to drop from the host for a long period of time. Pupation takes place in protected places on the surface of the soil and the pupal stage lasts from 40 to 60 days.

All *Gastrophilus* larvae are surprisingly resistant to chemicals. The treatment of horses with carbon bisulphide in three doses followed by a

physic is satisfactory if administered in late autumn. Spring treatment is less effective, as the full-grown larvae are more resistant, and many of the nose-fly bots have left the stomach and passed back to the rectum at that time.

Larvae of *G. haemorrhoidalis* may be removed from the rectum mechanically, but this is laborious. The use of enemas containing insecticides is ineffective.

As a repellent, pine tar mixed with other material gave good results against the common bot-fly and the throat bot-fly. Such mixtures may be utilised to cause the flies to lay eggs on parts of the body less accessible to the horse's mouth.

Various nose protectors are in use against *G. haemorrhoidalis*, but there are objections to many of them. A piece of leather suspended below the lips from the bit rings is simplest and best. For animals on pasture a halter with a box-like arrangement and throat cover has been devised to protect horses against infection by all three species.

Kerosene oil used as a wash is ineffective in destroying the eggs of *Gastrophilus*. A 2 per cent nicotine-sulphate solution was only partially effective. Nitrobenzine gas yields good results at 25, 24 and 10 hours' exposure, but only a small percentage was killed at 4 hours. The phenol compounds, by a contact application, seem to be the most effective in destroying young larvae and preventing the further development of embryos. Carbolic acid containing 2 per cent phenols is satisfactory for destroying eggs when applied to the infested parts of the host.

1258—Experiments in the Transmission of Trichinae in the U.S.A.—RAFFENSPERGER, H. B. (U. S. Bureau of Animal Industry, Chicago, Ill.), in the *Journal of the American Veterinary Association*, Vol. LIII, New Series, Vol. 6, No. 3, pp. 363-367 + Bibliography of 7 Publications. Ithaca, N. Y., 1918.

Certain workers (HÖYBERG, SALZER) have concluded that trichinosis may result from the swallowing of faeces or intestinal contents of animals harbouring the intestinal stage of the parasite. Other workers (LEUCKART, PAGENSTECHER, STÄUBLI) have concluded, however, that infection cannot be brought about through swallowing intestinal trichinae or the newly born larvae which may be found in the faeces of animals harbouring trichinae in the intestine. In the course of the author's investigations on trichinosis, he carried out some experiments similar to those of STÄUBLI. Rats and mice were fed on trichinous pork, and after their death, which occurred 2, 3, 4, 5, 7 and 10 days after the artificial infection, numerous live trichinae were found in the intestines. The contents of the duodenum and jejunum were fed to guinea-pigs; these were killed 40 to 50 days later, when their diaphragms were carefully examined under the microscope. The examination always gave negative results.

Concerning the stage at which trichinae in the muscles become infectious it is usually stated in the literature that non-encysted trichinae are not infectious. The author's results confirm this opinion:—rabbits, fed on trichinous meat, were killed 15 or 18 days later, when examination of

the diaphragm revealed the presence of many *unencysted* larvae. The fragments of the diaphragm were fed to other rabbits, which were killed after about 30 days; examination of the diaphragm, in this case, always gave negative results. But when the former rabbit had encysted larvae present in its diaphragm, that of the latter animal was also infected.

CONCLUSIONS: — The evidence obtained from the experiments supports the generally accepted opinions that trichinae are not transmissible through the faeces, that unencysted trichinae are not capable of developing when meat containing them is ingested, and finally that trichinae are spread from one host to another *only as a result of swallowing meat containing the encysted larvae of the parasites.*

1259 — **Cattle Lice and How to Eradicate Them.** — IMES, MARION, in *U. S. Department of Agriculture, Farmers' Bulletin* 909, 27 pp. + 14 Figs. Washington, February, 1918.

The bulletin under consideration treats of the following lice: — the short-nosed cattle louse (*Haematopinus eurysternus*), the long-nosed cattle louse (*Linognathus vituli*) and the common biting louse (*Trichodectes scalaris*). The life history and habits of each are described. When separated from their host the first two species live about 7 days, the third one only about 4 days. Newly hatched lice only live 2 or 3 days if they find no host. The longevity of the lice and the viability of their eggs when separated from their host are of great practical importance in their eradication.

The parasites detached from the animals drop in the corrals, stables and pastures, and through the adults die in about a week, the eggs may hatch if the weather is mild and continue to infect the herds. Infected stables should be cleaned and disinfected with coal-tar creosote suitably diluted. Animals which have been dipped or otherwise treated to free them from lice should not be taken to contaminated quarters or those they occupied previously unless they have first been cleaned and disinfected or left vacant for about 20 days.

Methods of controlling cattle-lice are: —

1) Hand applications: — *a*) dusting powders (naphthalene and pyrethrum), which are useful in holding the parasites in check when the weather is too cold for dipping or spraying; *b*) greases: — cottonseed oil and kerosene in equal parts;  $\frac{1}{2}$  pint of kerosene and 1 lb. of lard; crude petroleum; *c*) liquids.

2) spraying with a hand pump (or an orchard spray) with the liquids recommended for dips; two treatments should be given, 15 or 16 days apart.

3) Dipping in arsenical solution, coal tar creosote or nicotine.

The first two methods are suitable for small herds, the third (the most efficacious) is suitable for large herds. One arsenical or coal tar dip is usually sufficient to destroy the long-nosed louse and the common biting louse, but for the short-nosed louse two treatments at intervals of 15 or 16 days are necessary. The cattle should be well examined after the second dip as live lice sometimes remain and a third dip may be necessary about 16 days after the second.

The arsenical dip is made up of 4 lb. 85 % pure caustic soda + 8 lb.

99 % pure white arsenic in fine powder + 8 lb. sal soda crystals + 1 gallon pine tar + sufficient water to make 500 gallons. This dip is usually used cold, but, so as to avoid chills its temperature should be from 65° to 90° F.

Nicotine dips are very efficacious if they contain not less than  $\frac{5}{100}$  of 1 % nicotine; if dips more concentrated than 0.05 are used they are dangerous to the cattle especially if used hot. They are usually given warm, but their temperature should not exceed 110° F. Flowers of sulphur is sometimes added to nicotine dips; it dissolves very slightly and clings to the animal's skin for a long time, thus helping to prevent re-infection.

Two dipping plants are described, one in wood, the other in concrete; both are similar in their general design to that described by the author for sheep (1). The length of the vat varies from 24 to 100 ft. according to the number of animals to be dipped, the width is about 3 ft. and the depth 8 ft. A plant should include pens for keeping the cattle in before and after dipping. The passage ending in a chute which leads to the dip must be well designed. The two plans given show the measurements and detailed construction of the vat, and running and crowding chutes. The plant is completed by a heating system. Attention should also be given to the easy draining of the water.

**1260 - Avian Malaria Caused by *Plasmodium relictum* (Proteosoma); Experiments in Algeria.** — SERGENT, E. and E. (Pasteur Institute of Algiers), in the *Annales de l'Institut Pasteur*, Vol. XXXII, No. 8, pp. 382-388 + 2 Figs. Paris, August, 1918.

For twelve years the authors have studied at the Pasteur Institute of Algiers avian malaria caused by *Plasmodium relictum*, which in many ways resembles human malaria. They now publish the still incomplete results of the 560 experimental cases observed.

**INFECTION AND IMMUNITY.** — All the canaries (560) contracted the disease as a result of bites from infected *Culex* or by intraperitoneal inoculation of blood of an infected bird. The course of the disease is similar with both methods of infection:— period of incubation, 3 to 10 days; period of acute infection, 9 days, with 61.3 % mortality. Relative immunity.

**METHODS OF INFECTING THE BIRDS.** — 1) Intraperitoneal inoculation; 2) rubbing *Culex* on to the skin of the canary (in the proportion of 4 cases out of 10); intrarectal injection (1 case out of 6).

**MOSQUITOS SUBJECT TO INFECTION.** — The complete sexual evolution of *Plasmodium* may take place in *Stegomyia fasciata*, *Culex sergenti* Theobald, *Theobaldia spathipalpis* Rondani, *Acartomyia mariae* Serg. and Theob. (the larvae of which only live in the salt water of hol lows in the rocks along the coast of the Mediterranean). The passage of *Plasmodium* to the eggs has not been observed and there is no acquired immunity amongst mosquitoes.

A description is given of the trypanosome in the blood of the canary.

(*Serinus canarius* Koch), and of another trypanosome observed in the blood of the Algerian sparrow (*Passer domesticus* L.).

ANATOMY  
AND  
PHYSIOLOGY

1261 — **Complementary Studies on the Modification of the Germ Cells of Mammals; Effects of Inhalation of Alcohol Vapour on Guinea-pigs and their Progeny.** — STOCKHARD, C. R. and PAPANICOLAOW, N. (Department of Anatomy, Cornell Medical School, N. Y.), in *The Journal of Experimental Zoology*, Vol. XXVI, No. 1, pp. 119-226 + 10 Tables + 9 Figs. + Bibliography of 18 Publications. Philadelphia, 1918.

The results of researches carried out for over 6 or 7 years with the aim of observing the modifications produced in the germ cells of mammals by the constant inhalation of alcohol vapour. Other experimentors, especially PEARL (1), using a similar method, and technique to that of the author, have recently published the results of similar researches on other mammals or on birds. Although PEARL found the guinea-pig to be more sensitive to poisoning than fowls, the author is in agreement, speaking, broadly, with that experimenter whose results he discusses at length.

POULTRY

1262 — **Acorns as Food for Poultry.** — CRANFIELD, H. T., in *The Journal of the Board of Agriculture*, Vol. XXV, No. 5, pp. 573-576. London, August, 1918.

The use of acorns as a substitute for maize in poultry feeding is recommended. Acorns have recently been recommended as a cattle food and PETERMANN (*Die landwirtschaftlichen Versuchstationen*, Vol. LXXXII, Pt. 1-2, p. 93) considered them a suitable poultry food after having been dried and ground. In the autumn of 1917 acorns of different varieties were collected, dried over a hot-water tank for several weeks, ground and sifted (the husks being thus completely separated from the kernel). The kernel (80 % of the acorn) showed the following percentage composition on analysis: — moisture, 13.86; oil, 4.57; albuminoids, 7.88; soluble carbohydrates, 67.82; fibre, 3.63; ash, 2.24. The meal thus obtained was fed to twelve pullets and five two-year-old birds, all in full lay. Before the experiment they were receiving fish meal, sharps, cooked vegetables, wheat screenings, oats and maize. The grain and sharps were gradually replaced by crushed acorns and acorn meal. The experimental ration was continued for four weeks. The birds suffered no ill effects. The acorns are slightly binding but counteract the rather laxative action of fish meal. There was no great difference in laying.

It has been stated (*Fühlings landwirtschaftliche Zeitung*, 1904, p. 808) that if acorns are fed to hens in too large quantities they cause black discolouration of the egg yolk (2). This defect was not observed during the author's experiment in which each hen received daily 2 oz. of acorn kernel.

CONCLUSIONS. — Acorns contain no substance injurious to poultry. Their food value is equivalent to a mixture of oats and maize. They may completely replace grain in poultry feed if their slight deficiency in protein is made up.

1264—Silkworm Rearing in Indo-China.—GACHON, A., in the *Congrès d'Agriculture coloniale, Gouvernement Général de l'Indochine*, Hanoi Series, No. 7, 8 pp Hanoi-Haiphong, 1918.

SERICULTURE

The cultivation of mulberry and silkworm rearing has been practised in Indo-China since remote times and, in nearly all the countries of the Union, silkworm rearing might be greatly and rapidly developed. Many circumstances have contributed to making prosperous this essentially agricultural and home industry. The mulberry grows easily and develops well. The worms may be reared throughout the year in some districts and during at least eight months in the least favourable ones. Abundant, cheap labour and the free time left by the small variety of crops grown are very important factors in the possible development of silkworm rearing.

France buys annually in the Far East raw silk to the value of nearly £8 000 000, manufactures it and exports most of it as silk materials throughout the world. Indo-China might supply France very largely, as is shown by the quotations, with material equal to the best products of Canton, of raw silk and waste prepared by European methods chiefly in Tonkin and in Annam. These goods are already appearing on the French market. These considerations led the Government of Indo-China to encourage the improvement and development of the silkworm industry by all the means in its power, in order to export the produce to France.

The author (Inspector of the Agricultural and Commercial Services), after describing the cultivation of the mulberry and silkworm rearing in Indo-China (1), gives an account of the work done in the colony, especially by the Administration, to develop silkworm rearing. In 1905 the Administration appointed a silkworm egg specialist and founded an establishment at Phulang-Thuong for the production of eggs selected by the Pasteur method. At the same time pamphlets of a kind to be understood by the natives were drawn up in French, Quôc-ngũ, and Chinese. They gave simple, rational and practical methods for improving silkworm rearing, spinning and the preparation of waste, and were widely distributed in the silk centres and in all the provinces where they might have a useful effect.

Model and experimental silkworm nurseries and two egg-production establishments, one at Bach-hat (near Viêt-n) and one at Kiên-an (near Haiphong), were opened. The working of the egg-production centre of Phulang-Thuong, the oldest, best equipped and largest of the colony, was assured from 1907 to the end of 1916 by a commercial company controlled by the Administration and prepared to supply 3 000 000 layings. The establishment was taken under direct control on January 1, 1917, and its production exceeded 3 500 000 layings in 1917. The Bach-hat egg-production establishment, the second in importance, has been managed by the Administration since its foundation in 1914. It distributed free of charge

(1) This subject was studied by M. LEMARIS in the *Bulletin de l'Office colonial* and reviewed in R., Sept., 1912, No. 1330. (Ed).

600 000 layings in 1914, 1 000 000 in 1915, 1 650 000 in 1916, and about the same number in 1917. The Kiên-an egg-production centre was only established in 1916 and its production has reached 110 000 layings, in 1917 it exceeded 250 000. When the Phulang-Thuong establishment was opened a silkworm breeding research station was attached to it to study the introduction of foreign species, crossings, etc.

Of recent years Cochin-China, Annam, and Cambodia, following the methods used in Tonkin, have opened establishments for egg selection by the Pasteur method, model and experimental silkworm nurseries and plantations, as well as workshops for studying improved methods of silk spinning, the preparation of waste, and weaving for the European market. Since about ten years the Administration, especially in Tonkin, has made great sacrifices in order to develop the silkworm industry.

The silk-spinning basins has been altered and perfected giving as much consideration as possible to the native methods and customs. Many basins have been supplied free of cost to spinners who have thus been enabled to produce raw silk saleable in France either as they arrive or after a very simple system of re-reeling and re-boiling. The waste and by-products of the spinning industry, prepared by a rational, more profitable method than formerly, may now easily be exported to France. A premium of \$ 0.80 per kg. (about 9d. per lb.) was instituted in 1907 and continued till the end of 1915 in favour of steam spun or reeled raw silk exported to France, in order to help and encourage those engaged in the trade. There are three steam spinning mills in Tonkin: — 1) that opened in 1906 at Nam-dinh, the most important, with 100 basins; 2) that of Thai-binh, opened in 1909, with 40 basins; 3) that of Kiên-an, opened in 1915, with 60 basins. A fourth is to be built during 1918 at Viêtri. Large numbers of improved direct basins spinning for export, have been set up in the provinces of Nam-dinh, Thaininh, Ninh-binh, Hadong, and at Bach-hat. Certain mills, better equipped than others, have boilers for heating the water of the basins by steam, a more regular method than by wood, but the reeling apparatus is always on the model or that recommended by the Administration.

The European silk industry has been centred in Annam in the Binh-dinh, at Phuphong, near Quinhone, since 1903. A French company owns there a spinning mill with 100 spinning basins, a silk-twisting machine and a large weaving machine. All the products, raw silk, waste, and materials (crepe, crepon, pongee, etc.) are exported and sold in France.

The Annam Protectorate has installed in various silkworm rearing centres, small egg-producing establishments managed by native agents of the local Agricultural and Commercial Services under the direction and supervision of French officials of the Service. As in Tonkin these small establishments work in co-operation with the model silkworm nurseries, or obtain their supplies from rearers who have specialised in egg production.

In Cochin-China an Annamite company for spinning and weaving silk by European methods was founded at the beginning of 1914. A factory was built for receiving the material which has not yet been delivered, owing to present conditions. The Orphanage of the Sisters of Culac-Giêng has a

hand-weaving factory and a factory for crepons, pongees, figured silk and silk embroideries for the European markets. In spite of somewhat primitive equipment the products of this industry are very satisfactory and find a ready sale. The local body of the Agricultural and Commercial Services has two egg-production centres, one at Saigon and one at Tân-Châu, supplied by model silkworm nurseries belonging to the Administration and expert rearers. Many model nurseries and mulberry plantations, each having a small factory for silk spinning and weaving by improved native methods, have been established in silkworm rearing centres. Each year the Agricultural and Commercial Services of Cochin-China distribute gratis an average of 1 million selected layings. Cambodia has an egg-production establishment supplied with cocoons from model nurseries or produced in chosen centres by careful breeders. The selected eggs are distributed free of charge to all breeders who apply for them, an annual average of 1 million layings being distributed among the silkworm districts of Cambodia.

A silkworm-rearing research station has been opened at Phnompenh and has already given interesting results. Varieties of native worms have been most carefully selected and have given very strong white and yellow types of very pure colour. The experimental spinning and weaving factory has attracted the attention of the French and Cambodian populations and a company was recently formed to start a steam silk spinning factory with 100 basins and, later, a factory for machine weaving.

The reduction of the taxes on mulberry plantations made in 1905 by Governor General BEAU has given good results but less far-reaching than was expected, by reason of the native communal organisation and the payment of taxes by villages. The conferment of honorary rewards, of small grants and prizes given in competition would appear to have more opportunity of starting a movement for the extension of mulberry plantations and the improvement of silkworm rearing methods and the silk export industry.

For several years the "Musée agricole et commerciale" of Hanoi, belonging to the Agricultural and Commercial Services of Tonkin, has given professional instruction to numerous Annamites. A model silkworm nursery and mulberry plantation, a set of direct basins and several improved weaving looms, make it possible to follow the full cycle of the silk industry. This instruction has proved most useful and many Annamites owe new means of earning to it. It has made possible small home industries which need no help from the Administration. Although the silk industry workrooms of the Hanoi Museum have had to make room for other trades, equally interesting as home industries, the instructors continue their work in the province and also in other countries of the Indo-Chinese Union (Cambodia, Cochin-China, Annam).

All Indo-China is wonderfully well suited to the development of the silk industry. A large market for the products is assured as raw silk materials have taken first place among the exports of the Far-East to France and woven silk materials are the most important exports of France. The

export of raw and woven silk to France did not exist about ten years ago; now its value exceeds 1 million francs (£39 649) for Tonkin and ½ million for Annam. Some Chinese merchants export native silks and silk waste to Hong-Kong, Malaya and Siam. This trade has decreased greatly in Tonkin and Annam, but is still flourishing in Cambodia and Cochin-China. It is to be hoped that it may be completely replaced by an industry exporting all its products to France.

## FISH CULTURE

**1265 — Complementary Notes on Fish Breeding in Rice Fields, in Madagascar.** — LEGENDRE, J., in the *Revue Agricole et Vétérinaire de Madagascar et Dépendances*, Year III, No. 19, pp. 227-228. Tananarive, 1918.

Further advice is given (1) on the breeding of carp in rice fields, recommended both as a source of extra food for the natives and as a means of destroying mosquito larvae which live in the irrigated crop and transmit malaria (2). The carp are put in the rice fields eight days after transplanting if possible, and, at any rate, as soon as the water is there permanently. The depth of water most favourable to the growth both of the rice and the carp is from 3 to 6 inches. If the fish are about 3 inches long, two should be placed per square metre (1.19 sq. yards), if they are smaller, four or six per square metre. It is wise to put in some 2-inch long fish as these have reached the age for reproduction and may spawn in the rice fields (spawning in September, October and November).

To keep the fish in the field the holes by which the water enters and leaves it must be covered with wicker-work made with branches 0.04 to 0.08 inches apart, either crossed, or arranged parallelly and vertically and joined transversally. After the harvest the fish are collected, the largest (at least 3 inches without the tail) eaten and the rest placed in a reservoir till the next rice season. This reservoir may be a hole dug in the soil capable of holding at least 11 lb. of carp per cubic metre (1.30 cubic yards) of water, but a small pond is preferable. The fry feed on the aquatic animalcules, which the larger fish of the rice fields refuse, so that the fish production of the field is increased.

The author estimates that a well-stocked rice field should yield in four or five months ten-times the weight of fish it received.

**1266 — The Fennec Fox in Captivity to Replace the Domestic Cat.** — CRÉPIN, P., in the *Bulletin de la Société Nationale d'Acclimatation de France*, Year LXV, No. 8, pp. 225-228. Paris, August 18, 1918.

The fennec fox (*Canis zerda*), so little known at present, is of a certain interest. This pretty little North-African fox is easily tamed and, though it is not common, would be of great service to agriculture could it be reared.

It destroys cockchafers, locusts and crickets, all kinds of injurious insects, rats, it is as clean as the cat, requiring no previous training;

(1) See R. May, 1917, No. 472. (Ed.).

(2) To control malaria the breeding of other species has also been recommended, amongst them *Gambusia affinis*, a hardy, tiny fish, doing well in shallow water and in ponds containing less than 1.14 inches of water. See R. March, 1918, No. 251. (Ed.)

it takes up little space, does not smell, eats almost any thing, destroys less small birds than the cat, for it cannot climb trees, and is a pleasant companion, with a fine coat. It might well replace the cat as it has more advantages without the serious defects of the latter.

## [FARM ENGINEERING.

AGRICULTURAL  
MACHINERY  
AND  
IMPLEMENTS

1267 - Trials of Machines for Cultivating Vineyards Organised at Montpellier and Roche-de-Brun, France, in 1918. — I. FERROUILLAT (Director of the National School of Agriculture at Montpellier), in *Feuille d'Informations du Ministère de l'Agriculture*, Year XXIII, No. 25, pp. 6-7. Paris, June 18, 1918. — II. CASTEX (Director of the Vienne Agricultural Department), *Ibid.*, Year XXIII, No. 30, pp. 3-4. Paris, July 23, 1918.

1. — The trials took place in May in a vineyard on the Rochet estate, near Montpellier, in an easy, sandy soil in perfect condition. Part of the vines are planted about 50 in. apart in the lines, which are 6 ft. 6 in. apart; there are headlands from 13 to 16 ft. wide at each end and the rows are from 812 to 1 000 ft long, thus providing favourable working conditions for tractors.

The CHAPRON TRACTOR (1), which took part, was tried with a small 3-furrow OLIVER plough working a width of 28 in. and a spring tine Canadian harrow covering a width of 59 in. While there M. CHAPRON designed a machine capable of cultivating the whole space between the lines (69 in.), which consisted of a triangular frame, in the centre of which in front was fixed a drill plough, while 3 small AUBERT ploughs (Montpellier) were fixed on each side like stubble ploughs, thus making 7 working parts in all. Although not quite successful, after a slight modification the machine improvised in this way did not work badly.

The tractor, tried with the 3 machines mentioned, worked perfectly and did no damage whatever to the vines. The last day was employed in dynamometric and fuel-consumption tests. The results, given in a table, show that the tractive effort per sq. decimetre (= 1.55 sq. in.) of section of the strip of earth worked is very low (60.7 lb. with the Oliver 3-furrow plough working 6 in. deep. and 57.8 lb. with the same ploughing at a depth of 5 in.; 32.8 lb. with the CHAPRON gang-plough working at 2 to 3 in. deep, and 46 lb. with the same plough loaded with 297 lb. and ploughing 5 in. deep; 45.3 lb. with the Canadian harrow working at 4 in. deep. As the soil was sandy, the surface layer was perfectly broken down. Occasionally the tractive effort attained high figures, but without decreasing the speed of the machine, thus showing that its limit of traction was much higher.

As regards fuel consumption, in a first trial, an engine standing still while running at 1400 revolutions per minute consumed 0.44 galls. of petrol (density: 0.730) per hour; in 2 other trials the tractor, towing the 3-

(2) See R., October, 1918, No 1145. (Ed.)

furrow OLIVER plough and ploughing 5 in. deep in the one and 7 in. in the other (in relation to 28 and 32 in. of width and furrow lengths of 934.3 and 959 ft.) consumed 4.18 galls. in the first trial and 4.65 galls. in the second, which corresponds to 1.18 and 1.50 galls per acre of vineyard.

In the first trial the speed was 1.86 miles and in the second 2.37 miles. The time theoretically required to plough 1 acre of vineyard was 94 minutes in the first case and 70 minutes in the second ; in practice  $\frac{1}{3}$  more is needed, giving 125 and 93 minutes respectively.

The author observes that the fuel consumption of the engine is neither the only nor most important factor in judging the value of a tractor. The essential is to have a well-built strong machine with parts of easy access and maintenance, even if it does consume more petrol than another machine. Moreover, the fuel consumption varies from one machine to another and depends, in a certain degree, on the skill of the driver.

The CHAPRON tractor has a low fuel consumption and has some good points in its construction. The author thinks, without giving a final opinion, that the tractor seems suitable for viticultural work and is well worth note.

II. — Eleven makers had entered in June for the tests at La Roche-De-Bran (Vienne), but, owing to transport difficulties only 7 machines actually took part.

The Roche-de-Bran estate vineyard has a marly, slightly stony soil which is in very good condition. The vines are planted in rows 6 ft. 6 in. apart. Part of the vines are trained on iron wire. The branches are attached to the pole that supports each plant ; the long branches are propped between the plants in the direction of the lines, which increases the difficulty of mechanical cultivation. The lines are 600 ft. long and the headlands are 13 ft. wide. Plots of about 5 acres each were numbered and allotted, by drawing lots, to each the makers taking part in the trials.

In 1917, only two foreign-made machines for the mechanical culture of vineyards took part in the Mettray (1) trials ; at La Roche-de-Bran 4 French makers showed quite new types of machines, which show certain progress in adapting the tractor to vineyard cultivation. The author recalls that in order to plough 4 to 6 in. deep and scarify 2 in. deep in hill or plain vineyards, M. RINGELMANN, in his report on the mechanical cultivation of vineyards (2), estimates that the machine should have a maximum width of 3 ft. 3 in., while the tractor and the machine it hauls (plough or cultivator) should be able to turn on a headland no wider than 10 ft., the total weight of the machines not being greater than 2420 lb. These tractors should also be utilisable for sulphating, sulphuring and road transport. In addition when hoeing and weeding drilled crops it is necessary that the distance between the front wheels and the back wheels can be modified so as suit the width of the drills. The outer edges of the tyres should be about 8 in. from the axis of the seed-bed or of the plantation to be hoed or weeded.

Amongst the machines tested the author describes ; —

(1) See R., 1917, No. 940. (Ed.). — (2) See R., 1917, No. 841. (Ed.)

1) the 12-20 H.P. Cleveland (1), chain-track tractor, presented by the ALLIED MACHINERY Co. of France, 19, rue de Rocroy, Paris.

2) The tractor entered by the AMERICAN TRACTOR Co., 11 and 13, avenue du Bel Air, Paris.

3) the CHAPRON tractor (2) which ploughed and scarified the vineyard as well as ploughing 8 in. deep with a 2-furrow plough in ordinary soil and hauled with ease a mower for cutting hay in a meadow.

4) the vineyard tractor of the COMPTOIR ANGLO-FRANCO-RUSSE, 19, Avenue de l'Opera, Paris; 4 HP. at the pulley and 1.25 HP. at the draw-bar; runs at 230 to 2000 revolutions per minute, 0.93 and 3.1 miles per hour on the road, 0.6 to 1.8 miles on ploughed land; weight 451 lb.; height 3 ft. 3 in. This machine hauled a machine-hoe that hoed and weeded in two successive turns on the same strip.

5) the tractor entered by MM. F. GROS & BOUCHARDY fitted with a 10 HP. DESSAULES engine, running on paraffin or petrol.

6) the PAX motorplough of MM. FRANFORT & SEGUIN, 144, Rue de Charonne, Paris. The 2-cylinder vertical 6-8 HP. engine of this tractor runs at 800 revolutions and is placed in front of the axle; the makers state that it requires 3.3 galls. of petrol and 4.4 lb. of oil per day. The tractor is guided by means of 2 stilts placed behind the frame. Its total width is 3 ft. 3 in., its length is 10 ft. 6 in. and its height 3 ft. 3 in.; it weighs 1650 lb.

7) the No. 1 "Simplex Viticultural" tractor of SCHWERTZER & Co., 86, rue de Flandre, Paris, is built especially for cultivating vineyards; it is only 2 ft. 9 in. broad, as that it can easily pass amongst the rows of vines. The machine hauled a Canadian harrow and a vineyard plough. The implements hauled can be controlled directly by the driver without him having to leave his seat. The 4-cylinder, 10 HP. engine has 2 speeds and its single reverse runs at 2.5 to 3.1 miles per hour; the two driving wheels are braked separately. The tractor weighs 1540 lb. and it is 8 ft. 3 in. long; its declared fuel consumption is 0.88 to 1.1 galls. of petrol per hour.

All these machines worked well during the test period, without damaging the vines in spite of the difficulty resulting from the fact the long branches were supported over the soil and might have been caught by the working parts in passing.

**1268 - Tractor Operating Data in the U. S. A.** — *Official Report of the University of Illinois, Division of Farm Mechanics, in The Implement and Machinery Review, Vol. XLIV, No. 520, p. 412. London, August 1, 1918.*

Early in 1917 the Division of Farm Mechanics, the University of Illinois, U. S. A., sent to 60 tractor operators in the State of Illinois record sheets, arranged for the purpose of enabling the farmer to keep a yearly record of his tractor operations. When returned, 22 reports were found to have been carefully kept. A summary of the data obtained is given in the appended table. It should be remembered that these data have been ob-

(1) See R., October, 1918, No. 1145. (Ed.) — (2) See R., October, 1918, No. 1145. (Ed.)

tained from a limited number of successful operators. In only one case (tractors with kerosene-burning motors pulling 3 ploughs) is the number of operators large enough to warrant the drawing of general conclusions.

*Summary of tractor-operating data, Illinois, 1917.*

Fuel used	Gas	Gas	Kerosene	Gas	Gas

**SIZE OF TRACTORS.**— One tractor was of 6-12 H.P., 4 were of 8-16 H.P., 9 of 10-20 H.P., 6 of 12-25 H.P., 1 of 20-40 H.P., and 1 was of 25-40 H.P. Three of the users of 8-16 H.P. machines desired a larger tractor; 3 users of the 10-20 tractors believed that a larger machine would be better adapted to their conditions; only 2 men, one using a 10-20 and the other a 20-40 desired a smaller machine.

**TYPES OF DRIVE.**— 21 machines had wheel drives and 1 had a caterpillar type of drive. Sixteen of the 21 wheel machines had 2 drive wheels. Of the 5 operators whose machines had other than the 2-wheel drive, 3 expressed preference for a 4-wheeled machine with 2 drivers.

**Hired Help.** — The hired help bill was reduced by 10 farmers. The amount of reduction reported varied from  $\frac{1}{3}$  to  $\frac{2}{3}$  of the previous help bill. One farmer operating 320 acres reported that he had been able to dispense entirely with the services of one man.

**Soil Packing.** — 10 operators reported no soil packing; 6 reported packing when the soil was wet; 2 reported packing of maize ground; 3 reported beneficial effects from packing, and one made no report on this question.

**Price of Tractors.** — Practically all the machines were purchased at pre-war prices. To-day the same machines would cost from 60 % to 100 % more, which would materially increase the depreciation charge.

**Trouble.** — The % time-trouble is obtained by dividing the hours trouble by the hours used and multiplying by 100. The relatively large % time-trouble reported for gasoline tractors pulling 3 ploughs is due almost entirely to one operator who used a tractor having a 2-stroke cycle motor. Omitting the report of this man the % time-trouble for this class of machine is 4.15.

**Depreciation.** — The annual depreciation is estimated at 20 % of the original cost of the tractor.

**Interest.** — The interest (6 % per annum) is thus estimated: — Add the original cost and the annual depreciation; divide this sum by 2; and multiply the quotient by 0.06.

**Horses.** — Fifteen of the 22 operators replaced one horse or more by the use of the tractor. These data indicate that on the average a man farms 22 crop acres per horse without the use of a tractor and 29.7 crop acres per horse when the tractor is used. Nine operators stated that the tractor enabled them to use either lighter horses, more brood mares or young horses.

**1269 — The "Fiat" Tractor.** — SIGNORINI, M., in *Il Coltivatore*, Year LXIV, No. 24, pp. 503-504 + 1 Fig. Casale Monferrato, August 30, 1918.

The Italian-made "Fiat" tractor was tested successfully on August 21, 1918 at the Marchesa farm near Turin.

This tractor, shown in the appended figure, is of 18-20 H.P.; the engine has 4 cylinders (100 × 180) and it has 3 speeds — 1.4, 3.1 and 3.7 miles per hour; it weighs 5280 lb. and has a draw bar pull of 3960 lb. in the first speed and 2200 lb. in the second; it is 53 in. wide. Towing a 3-furrow plough at 8 in. deep it can plough 64 584 sq. ft. per hour, consuming 19.8 lb. of paraffin. This tractor can be used for towing vehicles on the road as well as for hauling machines for cultivation and for gathering crops. In addition, by means of a pulley, the "Fiat" tractor can be used to drive threshers and fixed farm machinery.

According to the author, the "Fiat" tractor has been built to meet the needs of Italian agriculture; it is strongly made, easily handled and smooth running; it suits large and medium sized farms.

The price of the tractor is not yet fixed, but it will not cost more than the foreign tractors imported into Italy.

"Fiat" tractor at work.

1270 - **The Haulage of Ploughs.** — RINGELMANN, M., in the *Comptes Rendus de l'Académie d'Agriculture de France*, Vol. IV, No. 27, pp. 746-748. Paris, July 24, 1918.

The author has previously shown that ploughing requires 80 % of the total energy necessary for cultivation.

Suitable weather for ploughing is generally limited in extent. Ploughing is not done under good conditions unless the soil contains from 9 to 10 % of water, 11 to 17 % being considered the optimum; at more than 21 or 22 % of water, the ploughing becomes bad. The water content of the soil, apart from the purely cultural point of view, has an influence on the wear of the parts, on the stability of the machine and, above all, on the tractive effort required by the plough.

As regards wear, in a good light potato soil (tertiary soil of the Grigny Plateau, Seine-et-Oise, France), the ploughshare has to be set 6 or 7 times per acre in dry summer weather. Each setting cost about 7*d.*, working out at 3*s.*6*d.* to 4*s.*1*d.* per acre. In September, when the soil is wet by the rains, one setting suffices for about 3 <sup>3</sup>/<sub>4</sub> acres. Under the conditions of the present case one share is completely worn out after ploughing 44.5 acres and to replace it costs 6*s.* 3*d.* for ordinary steel and 10*s.* 5*d.* for hardened steel.

. The tractive effort per sq. decimetre of section ploughed increases

[1269-1270]

for the same plough in the same soil in measure as the soil dries (the average density is 2 304 in tertiary soil).

The tractive effort for the plough at different dates and for ploughings comparable one with the other as regards dimensions was 47 kg. per sq. decimetre for a soil water-content of 15.4 %; 46.1 kg. for 11.1 % of water; 70.7 kg. for 5.1 % of water; and 78.2 kg. for 3.8 % of water.

The shape of the working parts also influences considerably on the traction. Thus, on the same length, at an interval of half an hour, a plough requires, for the same ploughing, from 1.40 to 1.42 times the pull required by a model of better design or more suited to that particular soil.

As the periods during which the soil are in such a state of humidity as to work well are generally limited, power farming has the advantage that, with it, the farmer can work his land in the desired time.

**1271 - A Tractor Plough.** — DESSAISATX, R., in the *Journal d'Agriculture Pratique*, Year LXXXII, Vol. XXXI. No. 17, pp. 329-330 + 1 Fig. Paris, August 22, 1918.

When a vehicle moves up a slope its resistance increases with the steepness of the slope. The motor drawing the vehicle up the slope uses a certain amount of energy to move itself, so that there is a reduction of the amount of tractive energy available for the vehicle or machine to be towed. This loss is due to the elevation of the motor on the inclined plane and is independent of the nature of the motor. For example, a tractor weighing 6160 lb. which gives an actual pull of 1672 lb. on level ground, and hauling a plough requiring an average tractive effort of 440 lb. per furrow, will give a pull of 1320 lb. for 3 furrows and 880 lb. for 2 furrows on level ground.

If this tractor mounts a 10 % slope, its possible tractive effort drops to 1661 lb. owing to the decreased pressure of the driving wheels on the soil, and the tractor itself requires 616 lb., so that if it gives a pull of 1672 lb. on level ground, it can only give a pull of 1045 lb. when mounting, which is insufficient for opening 3 furrows, but more than sufficient for opening 2 furrows. The tractor must, therefore, be handled in such a way that, in ascending, only 2 furrows are opened, while, in descending, 3 furrows are opened at the same time.

Therefore tractor ploughs destined for use in steeply sloping land should be arranged in such a way that, by moving a simple lever, the number of plough bottoms working could be rapidly changed.

MM. DE LACOUR and FABRE, 4, Avenue de Villiers, Paris, have exhibited at the Noisy-le-Grand (France) official trials a GALLOWAY plough (1) built according to the principle described above. It is a 3-furrow plough, and, for slopes, the third plough can be raised by moving a lever, when only 2 furrows are ploughed.

In considering the application of mechanical cultivation to the uneven ground in Scotland, the Highland and Agricultural Society of Scotland had laid down the condition (2) that ploughs intended to work on hilly ground should be made in such a way that they could be quickly changed at the

(1) See R., Oct. 1918, No. 1145. (Ed.) — (2) See R., Feb. 1918, No. 199. (Ed.)

end of the furrow so as to plough 2 or 3 furrows according to whether the tractor ascended or descends the sloping field.

The GALLOWAY plough fulfills the condition, which is applicable to so much cultivated ground.

1272 — The Béfort and Gaillard Electric Ploughing Set. — *Le Génie Rural*, Year X, No. 83, p. 14 + 2 Figs. Paris, 1918.

In this system — now on trial near Paris — the electric current does not come from a section but from a generator forming part of the set. The makers thus use electricity as a mechanical organ acting at the point where

Generator.

Front view of windlass.

it is required, and give that organ all the independence of the other organs forming the set. They are thus able, just as with a petrol engine and with just as much freedom, to generate the power at the required place and when required.

By transforming the initial power into auxiliary current, the makers claim that the power actually available is much greater than the same power used as a tractor in direct traction.

The BÉFORT-GAILLARD system, using a single generator with a minimum cost, has the advantage of always giving direct traction, the generator serving equally as tractor for the set, and all the ploughs of the farm.

The set offered to the French Ministry of Agriculture consists of a steam-generator, working very smoothly and easily controlled. The generator is always supplied with water and coal for a 10 hour's run, *i. e.* for 1 day's work without further supplies. It thus forms a mobile station going where wanted, when it has to supply its 2 sub-stations.

Cable-ploughing sets with a single generator all require a return cable

Rear view of windlass.

Generator.

or a return pulley. By doing away with the return pulley MM. BÉFORT and GAILLARD obtain a yield of 86 % of energy available at the draw bar.

To provide for unforeseen resistances and all the strains of traction, a good amount of reserve power must be available. At a speed of 85 cm. per second — a good practical speed for all hard work — the tractive effort is 1800 kg. Taking as basis a 5-furrow balance plough working at a depth of 20 cm. and meeting a resistance of 55 kg. per sq. decimetre, the tractive effort is not over 900 kg.; the reserve power is thus amply sufficient meet all possible needs.

The BÉFORT and GAILLARD set have the following interesting characteristics: — front swingle-trees with automatic decentring, so that cable traction can be used (without an auxiliary return of the cable) for drilled crops; a draw-bar hook buffering and controlling the traction.

1273 - The "Once-Over" Quack Grass Killer. — *The Implement and Machinery Review*, Vol. XLIV, No. 520, pp. 415-416 + 1 Fig. London, August 1, 1918.

The QUACK GRASS EXTERMINATOR Co., 912, Andrus Building, Minneapolis, Minn., U. S. A., makes a new machine for exterminating weeds, particularly couch grass. By running this machine once over a field (whence its name), practically every vestige of crop-killing weed is said to be exterminated.

This new device, shown in the appended figure, resembles a tractor, but does not propel itself. Its petrol motor serves to operate the mechanism while the machine itself is hitched to a tractor or drawn by horses.

The machine consists of a framework mounted on wheels, carrying at its forward end an ordinary plough, minus the mould board, behind which

"Once-Over" quack grass killer.

is a toothed cylinder, followed in the rear by an elevator running backward and upward at an angle of about  $40^{\circ}$  into separating mechanism, which, in turn, is followed by a large circular sieve moving in an anti-clock direction as the machine travels forward. Inside the reel or sieve is a horizontal conveyor running to a perpendicular elevator swing in the rear of the machine for conveying the weed refuse into a wagon driven alongside.

The operation of the machine can be described as follows:— The plough share located at the forward end is 16 in. wide and set to run at a depth of 4 to 6 in.; the ribbon of soil cut is passed back, there being no mould board, and brought into contact with the teeth of the forward cylinder which cuts and shreds up the weeds and soil. At this point about 60 % of the soil is returned to the earth and the weeds, stalks, etc., are elevated into the separating machinery, where a system of separation, not unlike that of a

wheat or small grain threshing outfit, separates the weeds and 20 % of the soil, the latter being returned to the ground. All the weeds and roots and the remaining 20 % of the soil pass into the revolving sieve in the rear. The soil is completely lost through the meshes of this sieve, and the weeds are carried upward by the revolving screen and dumped into the horizontal conveyor, in which they are carried to the perpendicular elevator in the rear, where they are elevated into a vehicle to be carted away and burned, or otherwise destroyed.

A field is thus left in a condition free from all weeds, roots and other noxious growths and in a thoroughly tilled condition, ready to be sown at once if desired. The machine has a capacity of 3 to 5 acres per day, according to the nature of the soil, the thickness of the ground and the speed at which the machine is towed.

This new tool is said to be strongly made and should last from 5 to 8 years; its estimated cost is £ 200.

1274 **Motor-saw Mounted on a Hand-cart.** — *La Terre Vaudoise*, Year X, No. 27, p. 249 + 1 Fig. Lausanne, July 6, 1918.

Messrs MEGEVET of Geneva make a circular motor-saw for cutting fire wood; the saw is driven by a petrol motor, the whole being mounted on a small hand-cart.

MEGEVET motor-saw mounted on a hand-cart.

The motor is of the FÉLIX-MEGEVET type; it is simple, light and runs well. By adding another cylinder, the maker has improved on the old, one-

cylinder type. As is shown in the figure the MEGEVEY wood-sawing plant is completely independent and can be moved and set up anywhere in the forest or at the farm. Its small size enables it to pass easily into restricted spaces. Its easy transport and use gives it a claim for superiority over other systems.

The circular saw, with its roller-table and well protected blade, is very safe and easy to work. The engine drives directly on the shaft of the circular saw by means of a horizontal belt. The whole plant is strongly built and all the parts are easily accessible.

The engine consumes little petrol. By using this motor saw (1), great economy in labour can be made while the work is done more quickly.

**1275—The Marmier and Canonne Apparatus for Drying and Concentrating Liquids at Low Temperatures.** — MARMIER, L. (Assistant Director of the Pasteur Institute at Lille), in the *Annales de l'Institut Pasteur*, Year XXXII, No. 4, pp. 145-149 + 2 Figs. Paris, April, 1918.

Many liquids of organic origin, such as albumin, fresh grape must, milk, etc., can be kept a long time without any fermentation taking place if they are dried or even when sufficiently concentrated. To do this, they cannot be boiled at atmospheric pressure and often they cannot be heated to about 60°C without running the risk of changes taking place in their composition. To enable such liquids to be dried or concentrated at low temperatures while retaining all their properties MM. MARMIER and CANONNE have designed an apparatus (see Fig.) which is constructed as follows:—

The desiccator consists of a closed cylindrical boiler *A* with double walls *a* and *b* between which circulates hot water maintained at the required temperature. The upper wall *c* has an outlet tube *d* communicating by a pipe *e* with a condenser *p*; this would be, for example, a tubular condenser whose tubes are water-cooled internally. The steam given off in *A* condenses on the outside of the tubes and the liquid thus obtained is collected in a tank *q*. A vacuum pump maintains a suitable vacuum throughout the apparatus. The liquid to be treated, coming from a recipient *i*, having the tap *j*, is distributed through the boiler by means of a hollow shaft *f* traversing the gland *g* and rotated by the pulley *h* or a cog-wheel.

Several radial tubes *l*, fixed on the shaft and communicating with the hollow interior, end in a nozzle *m* spraying the liquid in a fine spray on the chamber walls *a*. A scraper *s*, carried by the arms *n*, is mounted on the shaft which carries it round when rotating. It touches the cylinder walls, removing the concentrated or dried liquid deposited on the walls by the spray. A second scraper *o* is placed at the lower part of the shaft, and is so placed as to bring the dried product into a recipient *w*, from which it is removed at the end of the operation by the plug *x*. The apparatus works in the following manner:—

(1) The motor-saw with 1-cylinder, 3-H.P. FÉLIX engine costs 2900 Swiss francs; that with a 2-cylinder 6-H.P. FÉLIX engine costs 3500 Swiss francs. (Ed.)

When the water-bath is at a suitable temperature, the tap *j* is closed, and a vacuum produced. The reservoir *i* is filled with the product to be dried or concentrated; the shaft is set turning, *j* is opened; the atmospheric

MARMIER & CANONNE apparatus for drying liquids at low temperatures, Section.

pressure forces the liquid into the hollow shaft and into the jets. The liquid is spread in a thin layer on the heated wall and quickly evaporates. The rate of spraying and the speed of rotation are regulated in such a way that the product deposited on the wall is dried or concentrated to the

required degree before the spray passes again. The scraper *st* removes the product, which falls to the bottom and is scraped into the recipient *w* by the scraper *o*.

For small flows, jets with very fine holes are used. As there is a certain minimum size, especially for viscous liquids or those containing solids in suspension, beyond which the jets become stopped up, a sufficiently large opening is used and, by means of a very simple mechanism fixed to the apparatus, the movement of the shaft and the arrival of the liquid are stopped once every revolution, the liquid being stopped just a little before the shaft. After a time sufficient for the product to evaporate, the mechanism sets the shaft in motion for a second revolution and allows the liquid to pass once more. Whether the apparatus works continuously or discontinuously, the final product is always exactly the same for the same temperature and degree of vacuum in the desiccator.

With this machine the author was able to concentrate large quantities of fresh grape must which have kept perfectly, without any previous sterilisation, for several years. It should be noted that owing to the intense evaporation of the liquid, the product treated is at a much lower temperature—about 20° to 26°C—while on the wall than the wall itself—36° to 45°C.

1276 — **The Eichenberger Electric Evaporator.** — AMSTEIN, J., in the *Schweizerische Obst und Gartenbau Zeitung*, Year XXXI, No. 18, pp. 221-222 + 2 Figs. Münsingen, August 1, 1918.

Since 1917, M. E. EICHENBERGER, of Neukirch-Egnach, canton of Thurgovie, Switzerland, has made an electric evaporator for drying fruit, vegetables and other agricultural products, which has worked successfully for a year.

As is shown in the figure the EICHENBERGER electric evaporator is shaped like a wooden cupboard insulated with eternit and fitted with a ventilating fan driven by a weak electric current; the bottom and walls are provided with heating elements and a heat regulator.

This evaporator is made in different sizes; the small models are in 3 sizes from 32 to 59 in. high; the model *a*, of 200 to 300 watts, can take from 6.6 to 14.2 lb. of material to be dried; model *b*, of 300 to 400 watts, can take from 14.2 to 22 lb.; model *c*, of 400 to 700 watts, from 22 to 40 lb. Their prices are 90 fr., 100 fr., and 150 fr. respectively. According to the size they take up to 16 trays.

The evaporator used by the author is the largest model, costing 1500 fr.; as shown in the figure, it contains 32 trays holding 264 lb. of apples or 154 to 220 lb. of vegetables. According to the product, from 7 to 24 hours are required to obtain the desired degree of dryness.

The author used the apparatus continuously day and night from September, 1917, to February, 1918 and later on for another 3 weeks. During all this time he dried 6600 lb. of apples, 660 lb. of prunes and from

15 200 to 17 600 lb. of various products. — french beans, celery, turnips, parsley, etc.

EICHENBERGER electric evaporator.

#### 1277 - Review of Patents.

TILLAGE MACHINES AND IMPLEMENTS. — *Brasil*: 10217 Three furrow plough; 10218 Ridge plough for cereal cultivation.

*Canada*: 183565 Disc harrow; 183670 Harrow lifter.

*France*: 487948 Combined cultivator and hoe replacing the plough and other implements; 488287 Device for utilising Brabant and balance ploughs for motor culture by combining them with light engines; 488309 Improvements to gang ploughs towed by cable.

*New Zealand*: 39192 Harrow; 39561 Subsoil-draining attachment for agricultural implement.

*Sweden* : 43134 Agricultural implement.

*United Kingdom* : 117140 Soil pulverising machine ; 117150 Coupling for motor-plough ; 117169 Balance plough ; 117660-117661 Ploughs and cultivators for attachment to 2-wheeled motor-tractors ; 117766 Lifting device for ploughs or cultivators drawn by motor tractors ; 117771 Wheeled carriage for receiving beams of plough shares or cultivator lines and for attachment to a motor-tractor ; 117856 Power cultivation of land by cables.

*United States* : 1271031 Lister plough ; 1271373 Plough ; 1271485 Dumping scraper ; 1271818-1272231 Rotary spaders ; 1272260-1272294 Harrows ; 1272905 Tractor plough ; 1273069 Spring governor hitch for plough.

DRAINAGE AND IRRIGATION. — *Sweden* : 43242 Ditching machine.

*United States* : 1273206 Ditching machine.

MANURES AND MANURE DISTRIBUTORS. — *Denmark* : 23289 Fertiliser distributor.

*United States* : 1270849-1271007 Fertiliser dropping device.

DRILLS AND SEEDING MACHINES. — *Canada* : 183902 Potato planter.

*United States* : 1272550-1273251 Planters ; 1273039 Potato cutting machine.

VARIOUS CULTURAL OPERATIONS. — *Canada* : 183993 Plant protector.

*Denmark* : 23310 Movable spring-tines for cultivator, horse-hoe, etc.

*France* : 488320 Orchard plough.

*United Kingdom* : 117548 Stake for supporting plants.

*United States* : 1270787-1273496 Wheel weeder hoes ; 1270802 Riding cultivator ; 1271292 Lister cultivator ; 1271882 Attachment for maize cultivator ; 1272567 Hand cultivator.

CONTROL OF DISEASES AND PESTS OF PLANTS. — *New-Zealand* : 40019 Garden spraying apparatus.

*Switzerland* : 79035 Cockchafer trap.

*United States* : 1270847 Boll weevil catcher ; 1271355 Insect trap ; 1271504 Palmetto-root and weed plough.

REAPERS, MOWERS AND OTHER HARVESTING MACHINES. — *Canada* : 183747 Basket for lawn mowers.

*Denmark* : 23159 Platform for binders.

*France* : 488234 Motor lawn mower.

*Switzerland* : 78915 Mower knife control mechanism ; 79032 Sheaf packer and binder.

*United Kingdom* : 117137 Fruit gathering device ; 117496 Improvement to side-delivery hay-raking and swath-turning machines.

*United States* : 1271705 Bean harvester ; 1271803-127867 Harvesters ; 1271845 Header attachment for tractor ; 1272007 Bundle-carrier for grain binders ; 1272095 Sickle attachment ; 1272140 Grain saving attachment for binder ; 1272360 Automatic trip for shocking machine ; 1272371 Kaffir-corn header ; 1272426 Shocker attachment for binders ; 1272617 Hay-rake for mechanical traction ; 1272628 Mower and harvester attachment ; 1272665 Grain-reclaimer ; 1272666 Mechanical hay shocker ; 1272711 Cord holder for grain binder ; 1272717 Seed harvesting machine ; 1272733-1273350

Maize picking and husking machines ; 1272875 Flax pulling attachment for harvesters ; 1272885 Attachment for hay rake ; 1273240 Maize stalk cutter and loader.

**MACHINES FOR LIFTING ROOT CROPS.** — *Denmark* : 23223-23307-23325-23326 Potato diggers ; 23250 Root digging and topping machine ; 23211 Turnip digger with elevator ; 23327 Topping device for sugar beet diggers.

*Sweden* : 39655 Potato digger ; 43016 Hand root-digger and topper.

*United Kingdom* : 117126 Potato digger and harvester.

*United States* : 1271076-1272604-1272986 Beet harvesters.

**THRESHING AND WINNOWER MACHINES.** — *Denmark* : 23234 Attachment for threshing machine.

*United States* : 1271545 Grain cleaner for threshing machine ; 1272790 Grain separator for threshing machine ; 1273462 Grain separator.

**MACHINES AND IMPLEMENTS FOR THE PREPARATION AND STORAGE OF GRAIN, FODDER, ETC.** — *Canada* : 183548 Grain loader.

*Denmark* : 23243 Straw-cutter.

*Switzerland* : 78916.

*United States* : 1272419 Hay and sheaf loader ; 1273040 Potato loader ; 1273065 Sheaf loader ; 1273312 Portable loader and elevator.

**FORESTRY.** — *Canada* : 183296 Brush cutter ; 183464 Brush cutter and stump remover.

*Sweden* : 43135 Stabilising device for hand saw while sawing ; 43217 Hand saw spring device for felling trees.

**STEERING AND TRACTION OF AGRICULTURAL MACHINERY.** — *Canada* : 183518 Wind mill ; 183831 Tractor.

*Denmark* : 23171-23179-23283 Wind mills.

*France* : 488228 Windlass for mechanical ploughing.

*United Kingdom* : 116855 Steam tractor ; 117114 Endless belt traction engine ; 117125-117699 Tractors ; 117662 Means for attaching a motor tractor to a binder.

*United States* : 1270826 Motor driven vehicle ; 1270991 Traction wheels ; 1271239 Traction belt-chain ; 1271546 One-side endless-belt tractor ; 1271661 Tractor attachment for farm implements ; 1272287-1272475-1272491-1273631-1273652 Tractors ; 1272592 Tractor attachment ; 1273035 Traction and power attachment for motor-car ; 1273350 Tractor attachment for automobile ; 1273470-1273519 Power transmission attachments for automobiles ; 1273582 Wind mill.

**FEEDING AND HOUSING LIVESTOCK.** — *Denmark* : 23153 Hog self-feeder.

*Sweden* : 43261 Calf feeder.

*United States* : 1272591-1273294 Horse shoes ; 1273305 Branding and dehorning squeezers for cattle.

**POULTRY FARMING.** — *United Kingdom* : 117329 Food for poultry, etc.

*United States* : 1271666 Incubator.

**APICULTURE.** — *United States* : 1273286 Horizontal honey extractor.

**INDUSTRIES DEPENDING ON PLANT PRODUCTS.** — *Brazil* : 10186 New process and device for preparing Madeira wine.

*United Kingdom*: 116994 Machine for stoning fruit; 117479 Vegetable cutting and slicing machine; 117557 Machine for filling bottles, cans, etc.; 117582 Machine for capsuling bottles; 117749 Machine for cutting and slicing lemons.

*United States*: 1271065 Baker's furnace; 1271269 Manufacture of non-alcoholic malt beer; 1271371 Preparation of yeast; 1271868 Pine apple fleshing machine; 1271914 Method of treating raw sugar juices; 1272750 Process for preserving fruits and vegetables; 1273120 Hemp drying rack; 1273293 Vegetable dye and process of making same; 1273395 Tobacco drying system and apparatus; 1273396 Heating and drying apparatus.

INDUSTRIES DEPENDING ON ANIMAL PRODUCTS. — *Canada*: 183568 Fish drier.

*United States*: 1271060 Process and formula for tanning hides; 1273662 Process of tanning.

DAIRYING. — *New-Zealand*: 33925 Milk ejector; 39983 Skim milk tank delivery apparatus.

*Sweden*: 43037 Device for separator delivery tank; 43068 Cream delivery control for centrifugal separator bowl; 43190 Churn and centrifugal separator combined; 43259 Improvement to a milking machine; 43262 Churn; 43277 Device for suction milking machine.

*United Kingdom*: 117307 Milking machine; 117355 Churn; 117557 Machine for filling bottles, cans, etc.; 117713 Apparatus for drying milk.

*United States*: 1271153 Milk pasteurizer; 1271367 Centrifugal separator; 1271544 Vacuum milking machine; 1273375 Method of testing milk.

FARM BUILDINGS AND EQUIPMENT. — *Canada*: 183329 Portable sheep fold and shelter.

*United States*: 1270879 Barn ventilator; 1273456-1273673 Wire stretcher.

## AGRICULTURAL INDUSTRIES.

INDUSTRIES  
DEPENDING

PRODUCTS

1278 — Analysis of Portuguese Colares Wines. — GONÇALVES DE SOUSA, J. V., in the *Revista Agronomica*, Year XIII, Series 2, Nos. 1-4, pp. 90-93 + 2 Tables. Lisbon, 1908.

To distinguish the Colares type of wine (1) the author analysed 127 samples of red wine and 23 samples of white wine from these vineyards. Below are given the averages of several determinations. The first figure for each value is for red wines, the second for white wines:—

(1) Colares (or Collares) wines are fine table wines from the vine-growing district of the basin and banks of the Tago. These remarkable wines are made almost exclusively with "Ramisco" grapes, considered the finest of Portugal. They form the basis of the Colares vineyards, 20 miles from Lisbon, on the sandy shore near Cintra. — B. C. CINCINNATO DA COSTA and D. LUIZ DE CASTRO, "*Le Portugal au point de vue agricole*", pp. 389-394. Lisbon, 1900. (Ed.)

*Alcohol*. — by volume, 11.14%, 11.99%; by weight, 8.84%, 9.49 %.

*Total dry extract* : — 23.41 gm., 18.61 gm. per litre.

*Total acidity* (expressed in sulphuric acid per litre) :— 4.65 gm., 4.37 gm.

*Fixed acidity* (expressed in tartaric acid per litre) : 5.96 gm., 5.78 gm.

*Volatile acidity* (expressed in acetic acid per litre) :— 0.95 gm., 0.93 gm.

*Ash* :— About 10 % of the reduced dry extract :— Red wine, 2.42 gm., white wine 1.88 gm. per litre.

*Phosphoric acid* :— In the ash of red wine, 0.20 gm., in that of white wine, 0.175 gm.

*Reducing sugar* : — 1.54 gm, 0.99 gm. per litre.

*Glycerine* : — 6.20 gm, 6.59 gm. per litre.

*Tannin* :— Red wine, 0.81 gm. per litre ; white wine, 0.002 gm. (it could be estimated in three samples only).

*Bitartrate of potash* (by BERTHELOT and FLEURIEU'S method) :— 1.93 gm. 0.75 gm. per litre.

Two tables show the results obtained for each of the 150 samples of wine analysed, and give the localities from which they came.

**1279 — A Study of the Viscosity of Various Colonial Oils.** — HEIM, F., in the *Bulletin de l'Office Colonial*, Year XI, No. 125, pp. 251-264. Melun, 1918.

The author, Director of the Colonial Production Investigation Service, reports work done by this Service. Certain colonial oils, such as castor oil, are of great value for lubricating purposes. As a rule, however, in the case of all fats, even those which are solid at normal temperature, it is necessary to ascertain whether the viscosity constants may be used to characterise and differentiate the fatty bodies. On the other hand the relation between the chemical properties of fats, their viscosity constants and other physical constants require to be defined. The study of the viscosity of latex, rubber solutions, etc. as well as of oils and fats, is of equal interest. Viscosity tests were made with a viscometer made on the same principles as that used for the study of the viscosity of solutions (1).

**CONCLUSIONS.** — Viscosity varies greatly with the temperature so that when viscosity determinations are being made variations in temperature should be guarded against. Comparative tests must be made at the same temperature. The viscosity of oils and fats varies with different physical properties. If oils are divided into three groups, drying, semi-drying and non-drying, the viscosity increases considerably with the density in each group. This also applies to fats.

The viscosity of an oil does not appear to depend on the solidifying point and, except in the case of very viscous oils, it increases with the point of melting or solidification of the fatty acids. In the case of fats it increases with the melting point of the fat or fatty acids.

The viscosity also varies with the chemical composition of the oil or fat and decreases as the oleic acid, i. e., liquid, content increases. It would be very interesting to mix acids or pure fatty glycerides and deter-

(1) See *Comptes rendus de l'Académie des Sciences*, July 8, 1912. (Ed.)

mine all their physical properties. The results would certainly throw much light on the complex question of the composition of oils and fats. Finally, the viscosity varies with the commercial constant known as the iodine value and, for liquid oils, is higher in proportion as this value is lower, i. e., as there are fewer liquid acids.

It should be noted that if liquid oils or fats obey fairly definite laws, this is not true of very viscous oils which sometimes behave as an oil, sometimes as a fat. More numerous experiments will make it possible to clear up this point and to confirm what is already known. In practice viscosity is not only a quality of a lubricating oil, but is also an important physical property for the industrial characterisation of colonial oils and fats.

**1280 — Oil of *Jessenia polycarpa* Nuts and *Caryodendron orinocense* Seeds, in Colombia.** — BACHARACH, A. L. (Wellcome Chemical Laboratories), in *The Analyst*, Vol. XLIII, No. 509, pp. 289-291 + 2 Tables. London, August, 1918.

In Colombia oil is extracted from the nuts of "sejen" (*Jessenia polycarpa* Karst). This oil is known locally as "aceite de sejen" (literally "oil of palm") and is said to be efficacious in chest and lung complaints. It is also used for cooking purposes. It is a pale yellow oil, with a slight fluorescence and not unpleasant smell. Analyses gave the following values: — Saponification value, 188.5; iodine value, 74.1; Hehner value, 93.8. It is seen that this oil is very similar to olive oil.

The seed of the Euphorbiaceae *Caryodendron orinocense* Karst, known in Colombia as "tacay" are eaten roasted. A chemical analysis gave the following results: — Water, 4.43 %; ash, 2.95 %; crude fibre; 2.40 %; oil (ether soluble), 53.20 %; proteins, 12.90 %. The flavour of the roasted seed is somewhat similar to that of burnt almonds, but rather more bitter.

**1281 — Note on Orange-Pip Oil.** — HEWER, D. G., in *The Analyst*, [Vol. XLII, No. 497, pp. 271-273. London, August, 1917.

In marmalade factories the pips are separated by centrifugalisation. Very few attempts have been made to use them commercially though it would be easy, after drying, to extract the oil from them either by pressure or the use of solvents. By the use of petroleum ether the author extracted from the pips 37.5 % of a golden-yellow, almost odourless oil, at first only slightly bitter, but becoming more so on keeping. The oil saponifies easily and should be suitable for the manufacture of soap.

An analysis of the oil gave the following values: — Saponification value, 193.7; iodine value, 100.3; specific gravity at 15°C., 0.9208.

**1282 — On the Composition of Fruit Juices.** — THOMPSON, F., in the *Delaware Agricultural Experiment Station*, [Bulletin No. 119 (Annual Report, 1917), pp. 18-19. Newark, February 1, 1918.

The author has attempted to estimate the citric, malic and tartaric acids in various fruit juices by means of the rotatory power produced with ammonium acetate or molybdic acid. Good results were obtained with pure solutions of the above-mentioned acids, but they did not agree with those obtained with natural fruit juices, probably because of

the rotatory influence of other constituents of the sugars themselves and because the molybdcic acid was reduced. Good results were given by the Prati method as modified by WILLAMAN for estimating citric acid. Preliminary studies of the hydrogen-ion concentrations of fruit juices at different periods of ripening gave constant results. This fact is considered as showing constant acidity. This invariability is probably necessary to allow the action of enzymes.

**1283 — The Industrial Utilisation of the Colouring Matter of Sweet Sorghum Glumes (1).**

— PRÉDALU, A., in *Comptes rendus des Séances de l'Académie des Sciences*, Vol. CLXVII, No. 9, pp. 345-348. Paris, August 26, 1918.

Towards 1850 the presence in the stem of sweet sorghum of a colouring matter giving a red dye was reported. This dye, known as "Baden red", was not used in practice. While studying sweet sorghum flour the author was struck by the colouring capacity of the acid juices which had been used during the hydrolysis of the starch, and tested this colouring matter on various fibres both mordanted and not. He found that the colouring matter could be extracted from the crushed glumes by treating them in the autoclave, under a pressure of 2 kg. per sq. cm., with distilled water containing 1 % of sulphuric or hydrochloric acid or 2 % of sodium bisulphate.

The colouring matter dyes wool, silk, leather and cotton. The acid juice dyes wool directly and silk by boiling, giving a fine salmon colour. A fine series of shades may be obtained by mordanting and intensifying. The shades thus obtained with wool and silk are bright and full, fast and easy to apply, giving beautiful shades varying from violet to fire red with a madder tint (lilac, claret, pink, amaranth, salmon), from fawn to a rich, pure brown, from pearl grey to dark grey. This colouring matter of the glumes of sweet sorghum, as well as that of several varieties of sorghum with black glumes, could no doubt be used advantageously for industrial purposes.

**1284 — Papaine as a Coagulant for Rubber.** — *India Rubber World*, Vol. LVII, No. 5, p. 311. New York, February, 1918.

Experiments were recently undertaken by ULTÈR to determine the value of papaine as a coagulant for *Hevea* latex. An aqueous solution of this preparation proved twice as powerful as an acetic acid solution of the same concentration. The vulcanisation period of rubber thus prepared is normal, but the rubber dries very slowly.

Papaine is the dried milk sap of the papaw tree, a native of Central America and the West Indies, but now introduced into most tropical countries. Papaine acts as a rennet and is sometimes used as a substitute for pepsin in medicine.

(1) See R. Feb., 1918, No. 172; R. April, 1918, No. 467; R. Oct., 1918, No. 1075. (Ed.)

- 1285 — **The Effect of Heat on the Citric Acid Content of Milk.** — SOMMER, H. H. and HART, E. B. (Laboratory of Agricultural Chemistry of the University of Wisconsin, Madison), in *The Journal of Biological Chemistry*, Vol. XXXV, No. 2, pp. 313-318 + 3 Tables. Baltimore, August, 1918.

OBERMAYER stated that boiling decreases the citric acid content of milk. The authors made experiments on the effect of heat on this constituent of milk to determine whether the decreased citric acid of boiled milk is responsible for scurvy or Barlow's disease (1) in children on a milk diet. Many workers (FUNK, GERSTENBERGER) consider the anti-scorbutic effect of certain fruit juices to be due to their high citric acid content.

Several milk samples were heated to different temperatures by different methods, and it was observed that even prolonged boiling (in the autoclave at 15 lb. pressure for 1 hour) did not affect the citric acid content, nor does heat change the salts of this acid to an insoluble form.

- 1286 — **Method of Counting Bacteria in Raw or Pasteurised Milk.** — ALLEN, P. in *The Journal of Infectious Diseases*, Vol. XXII, No. 3, p. 245, March, 1918, reviewed in *Office international d'hygiène publique*, Vol. X, No. 7, pp. 851-853. Paris, July, 1918.

Up to the present the practical bacteriological control of milk has been almost impossible. It could only be done by the general method of isolation on plates, a tedious method requiring at least 24 hours to give a result, and therefore inapplicable in general control as it would be impossible to enforce such a delay before allowing the sale of suspected milk.

The author described in detail a rapid bacteriological method of control which should render great service. An aqueous suspension of alumina mixed with milk holds the bacteria in a tube. By centrifugalising the mixture an alumina clot is obtained containing all the bacteria free from fat and casein. The residue is spread thinly on a slide and stained. As the alumina particles have little affinity for the  $\frac{1}{4}$  dilution of methylene blue stain used, the bacteria can easily be counted.

- 1287 — **A Method for Detecting Bird's Flesh in Meat Preserves.** — GAUTRELET E., in the *Industrie Française de la Conserve*, Year V, No. 22, pp. 217-220. Paris, June, 1918.

It is well known that the oxygen-absorbing respiratory pigment in animal blood varies in colour with the species and according to the intensity of the bio-chemical exchanges in the organism, i. e. it is a) blue through cupric albuminoid — haemocyanin, found only in the lowest animals, b) red through ferrous albuminoid — haemoglobin, only found in a few lower animals (in the free state in the blood) and in all the higher animals in special corpuscles. As the diameter of these corpuscles exceeds that of the largest muscular capillaries it is necessary for them, in order to circulate in the blood, to become deformed to a more or less considerable extent in conformity with the intensity of the biochemical exchanges in oxidation or heat which they have to assure to the organism. In most mammals the capillary "deformity" of the corpuscles is moderate and they are called *discoïds*.

(1) See R. Sept., 1918, No. 952. (Ed.)

In non-cyclostomous fish, reptiles, birds, camels and pacas this capillary deformity is more marked and the corpuscles are called *elliptoids*. The different animal species which have a respiratory pigment within the corpuscles can be rapidly and clearly divided into two groups by a simple microscopic examination:— those with discoid corpuscles and those with elliptoid corpuscles.

The differentiation may be carried yet further. Haemoglobin is never exactly the same in all animal species and the crystallisations of haemin hydrochlorate derived from it are different and typical for each higher animal species. The peculiar physiological properties of the albuminoids of animal tissues make it possible to obtain all the desired solution by means of anaphylactic injections.

The differential detection of animal flesh in meat preserves is, however, a particular one because the meat has been cooked and many workers have insisted that such detection is impossible under these conditions. Nevertheless the author has done so many times by the following method:— on a slide is placed a drop of physiological serum diluted with caustic soda in proportion to the average alkalinity of the blood serum of animals in general (220 mgm. per 100 parts), a mixture is made in the serum on the surface of the slide and, after about ten minutes a direct microscopic examination (without cover glass) is made with a magnification of about 400 diameters.

By these means it is possible to observe the blood in cooked preserves in the form of an amorphous mass of dissociated haematoidin, but also in the classical form of discoid corpuscles if it is a question of mammals (cooked black pudding), or with the haematoidin mass may be recognised elliptoid corpuscles, as in the case of preserves made with bird's blood (e. g. "sanguette fricassée", made of the blood of chicken or duck fried in butter with onions), or, with the haematoidin mass are seen both discoid and elliptoid corpuscles, as in the case of mixed preserve (e. g. blood of pigs and ducks mixed).

CONCLUSION. — A microscopic examination in an alkaline serum medium makes possible a generic detection of discoid and elliptoid corpuscles in the *cooked bloods*, either when *mixed* or *separated*, of mammals and birds, thus making it possible to distinguish easily the origin of the materials used in meat preserves.

LEGISLATIVE  
AND ADMINI-  
STRATIVE  
MEASURES  
FOR THE  
PROTECTION  
OF CROPS

1291 - Measures for the Control of Locusts, in Italy. — *Gazzetta ufficiale del Regno d'Italia*, Year 1918, No. 213, p. 2590. Rome, Sept. 9, 1918.

By the decree No. 1214 of July 14, 1918 of the Lieutenant-Governor of Italy which came into force on September 10 it was ordered that :—

Art. 1. — To art. 5 of the decree of June 26, 1913, No. 888 (1) be added the following paragraph : — “ The Ministry of Agriculture may order the control of locusts. According to art. 4 no indemnity is due and no previous order or notification need be made to landowners or managers ”.

Art. 2. — To art. 7 of the same law the following paragraph be added : — Half of the cost of controlling locusts shall be paid by the State which may advance the whole sum. The other half shall be divided between the Province and the invaded or threatened Communes.

When the State advances that part of the expenses incurred in the control of locusts which falls to the Province and the invaded, or threatened Communes, payment shall be by the methods and guarantees mentioned in the first articles of the present decree.

The Communes may contribute by loans, the value of which is deducted from the contribution to be paid by them. They are authorised to demand the necessary aid from citizens capable of work, paying those workers whose position calls for an indemnity.

When, in spite of its obvious necessity, the Communes refuse the aid, the Prefect, on the proposition of the delegates of the Ministry of Agriculture, may pass an order to deal with it.

Art. 3. — The decree, No. 529 of June 15, 1911, is abrogated from the day on which the present decree comes into force.

### DISEASES NOT DUE TO PARASITES OR OF UNKNOWN ORIGIN.

1292 - Root Rot of Citrus in the Oasis of Tripoli. — LEONE, G., in *L'Agricoltura Coloniale*, Year XII, 1st Half-Year, No. 4, pp. 209-215 + 4 Figs. Florence, 1918.

During his studies on the cultivation of blood oranges (“ *démme* ”) the author ascertained that root rot (“ *marciume radicale* ”) of citrus trees is very common in the oasis of Tripoli, where it has existed for some time.

(1) See R. Aug., 1913, No. 995. (*Ed.*)

It is difficult to distinguish affected trees because the disease is already very advanced before signs of it appear on the leaves. The first symptoms are hampered growth, thin twigs, slight yellowing of the leaves, abundant flowering followed by the fall of the flowers and leaves and the partial, then total loss of all the leaves. When the roots are uncovered a strong smell of putrefaction is noticed. The roots are badly diseased, blackish in colour, and soft and spongy. The bark is easily removed, and underneath there are white layers of mycelium. In most cases the affected tree dies. The disease is contagious.

In the soil of the oasis of Tripoli strata of more or less impermeable rock are found at various depths which the roots may reach. The irrigation water may remain more or less on these strata and, as the natives irrigate citrus trees copiously, water being given in summer every five days in quantities much exceeding the needs of the plants, the author considers root rot to be caused chiefly by excess of water. The trees may be rendered subject to the disease by the excessive use of manure containing faecal matter, the rapid fermentation of which may affect the cortical tissues of the roots. This would occur especially where citrus trees are grown in conjunction with vegetables. Whatever the original cause of the root rot may be, abundant irrigation favours its development. Its rapid spread is facilitated by the system of propagation used which usually consists in layering and, more rarely, in the use of cuttings.

The most important preventative measures are : —

- 1) When propagating by cuttings, use cuttings and healthy rooted cuttings from trees unaffected by the disease. The best and safest system, however, is to use plants grafted on bitter orange trees.
- 2) If well-made manure is not available it is best to use mineral fertiliser.
- 3) The roots should not come in contact with the manure.
- 4) Irrigation should not be excessive but reduced to the absolute minimum required.
- 5) Herbaceous plants needing much moisture and organic manure, such as vegetables, should not be grown in conjunction with citrus trees.
- 6) Trees should not be replanted where there are any dead roots.
- 7) Trees should not be planted too deep.
- 8) The plantations should be constantly examined because, if the disease is discovered in its early stages, it may be controlled, in some cases at least, by isolation and care of the plants attacked.

1293 — Disease of the Elm and Nettle Tree, Observed in Italy. — PANTANELLI, E., in *Le Stazioni sperimentali agrarie italiane*, Vol. LI, Pt. 3-6, pp. 214-219 + 2 Plates.\* Modena, 1918.

In August, 1915 the author observed an apparently new disease on young elms and nettle trees (*Celtis australis*) grown uninterruptedly for several years in the Royal Nursery of Aquila. Young elms one to two years old were stunted with short, thin twigs with short internodes, and very developed secondary branches which gave the trees a bushy appearance. The

leaves were very small, covered with small, transparent, yellowish spots, irregular and of varying thickness, generally thinner in the pale areas.

The upper part of the nettle tree was chiefly attacked, and was also stunted, the internodes being short, the branches thin and the development of the secondary branches more rapid than in normal plants. The leaves too were smaller than normal ones, deformed, twisted, wrinkled, and covered with spots of a yellowish-green even in reflected light. The leaves were thinner in the pale areas. Neither on the young trunks nor on the roots was there any sign of an insect or plant parasite, or of any histological disease of these organs. The roots were few in number, little branched, but healthy.

When the stunted trees were transplanted in fresh soil the disease disappeared or diminished more easily in the nettle tree than in the elm, but the growth of the diseased plants was slight, and often they did not survive.

The author has observed in Emilia on several occasions a disease similar to that found in the nursery at Aquila, but, instead of attacking young plants, it attacks the last annual buds of adult trees. These buds are so stunted as to look like "witch's brooms". The author believes this disease to be caused by functional disturbances.

## DISEASES DUE TO FUNGI, BACTERIA AND OTHER LOWER PLANTS.

### GENERAL.

- 1294 — **Fungi of the Valley of San Martino or the Valley of Germanasca, Piedmont, Italy** (1). — PEYRONEL, B. in the *Nuovo Giornale Botanico Italiano*, New Series, Vol. XXV, No. 2, pp. 146-192. Rocca San Casciano, 1918.

This second contribution to the study of the mycological flora of the Vaudois Valleys of Piedmont gives a list of 128 species of macromycetes and micromycetes almost all of which were collected in the Ricaldetto district, mostly at altitudes above 3280 feet, during July, August and September, 1914, and August and September, 1916. Seventy-two species are new to the district, and one is new to Italy. The description of most of the species is followed by morphological and biological observations.

- 1295 — **Fungi from India, Malaya and Africa.** — Royal Botanic Gardens, Kew, *Bulletin of Miscellaneous Information*, No. 6, pp. 207-210 + 8 Figs. London, 1918.

Nine species from India, Malaya, Africa, and Australia are described in the present note, apparently as new to science.

The following species are worthy of special mention:—

- 1) *Fomes elegans* Wakefield, on living *Shorea rubusta* ("Sal") at Singbhum; this polyporus is not reported to have caused serious damage;
- 2) *F. pseudo-ferreus* Wakefield; the cause of a serious disease of the

(1) See R., February, 1917, No. 191. (Ed.)

roots of *Hevea brasiliensis* in Malaya; the disease in question was first attributed to the action of *Poria hypolateritia*; unfortunately the material available at present is imperfect and it seems that perfect fructifications are rarely formed; when well developed ones are available, the description given may have to be revised, but as the species cannot be identified as any known form, a name has been given to it in the interval;

3) *Puccinia Coreopsidis* Wakefield, on *Coreopsis*, in Uganda;

4) *Cercospora latimaculatus* Wakefield on leaves of *Bauhinia* at Aburi (Gold Coast).

1296 — On the Life History of the Rose Blotch Fungus (*Actinonema Rosae*), in Great Britain. — ALCOCK, N. L., in the *Royal Botanic Gardens, Kew, Bulletin of Miscellaneous Information*, No. 6, pp. 193-197 + 2 Figs + 1 Plate. London, 1918.

Work on the control of *Actinonema Rosae* (1). — which, according to WOLF does not belong to the genus *Marssonina* (2) — has till recently been hampered by lack of knowledge of its life cycle and the origin of the new attack each season. This problem was solved for the United States by WOLF (1912) who found on dead rose leaves an ascigerous stage, for which he formed the genus *Diplocarpon* (3) belonging to the family *Microthyriaceae*. The perithecia ripen in April and the ascospores formed in them infect the young foliage as it unfolds. There did not appear to be an ascigerous stage in Great Britain, where repeated investigations into this subject had always given negative results. When pruning Juliet roses in the spring of 1918 a patch of discoloured tissue, apparently caused by a fungus, was noticed on the young wood of the previous season. A microscopical examination showed these patches to contain abundant mycelium and compact masses of fungus-tissues bearing spores of *Actinonema Rosae* (4).

The season was well advanced before the infection on the young wood of Juliet was first observed. The roses in most of the gardens had already been pruned and it was no longer possible to obtain much more material or to make a complete list of the varieties affected. The fungus is scarce in the Royal Botanic Gardens, Kew, and appears to die soon if introduced into the neighbourhood. A visit to the Gardens of the Royal Horticultural Society at Wisley showed the wood of the following varieties to be attacked: — Madame Ravary, La Tosca, Mrs. David Jardine, Gruss an Teplitz, and Juliet.

It is not sufficient to collect and burn infected leaves, attention should also be given to the wood of the preceding years and, if it be infected, it should be cut. Experiments in America have also shown that dusting eight times a year with a powder composed of 90 parts of finely ground sul-

(1) See R. April 1911, No. 1294. (Ed.)

(2) See R. June, 1913, p. 879; R. Nov., 1914, No. 1073. (Ed.)

(3) See R. Dec., 1915, No. 1350. (Ed.)

(4) From 1914 onwards was observed in France in the tissues of the stem mycelium attributed to *Marssonina Rosae* and it was henceforth considered that this mycelium might be perennial. See R. Nov., 1914, No. 1073. (Ed.)

phur, and 11 parts of arsenate of lead is very effective in controlling blotch. Bordeaux mixture and lime sulphur are also satisfactory, but disfigure the plants. In badly-infected gardens it is advisable to use a fungicide even if the trees have been carefully pruned, because some pustules are almost certain to have passed unnoticed and spores may be carried from neighbouring gardens by the wind. It is most important to begin spraying early to prevent the fungus from entering the leaves because, should this occur, the mycelium continues to grow in the tissues and the blotches follow inevitably. American experiments have shown that, to protect the trees completely, it is necessary to spray at intervals of about a month.

RESISTANT  
PLANTS

1297 — **Specific Resistance of Different Varieties of Spring Wheat to *Fusarium culmorum* in Sweden.** — ÅKERMAN, Å., in *Svenskes Utsädesföreningens Tidskrift*, Year XXVIII, Pt. 2, pp. 82-89. Malmö 1918

In 1917 spring wheat in South and Central Sweden suffered severely from attacks by *Fusarium culmorum*. According to the author this was due to two causes:— 1) the seed from the 1916 harvest was already badly infested by the *Fusarium* which developed in the damp, rainy weather which prevailed during the harvest; 2) the great drought of the spring of 1917 which greatly weakened the plants, thus making them more subject to disease.

Not all the varieties examined behaved in the same way. The most immune varieties were 0850 (of Sol × Svalöfs Kolben), 0841 *b* (new strain of Extra Kolben), 0810 (of Värpär × Brunt Schlanstedter). These were followed by 0805, 0821, 0821 *b* (of Värpär × Svalöfs Kolben), 0841 (Extra Kolben), Marquis, and a native spring wheat from Dalarna.

The most susceptible (judged by the number of diseased seedlings) were:— 0201 (of Emma), 0804 (of Emma × Värpär), Värpär, Svalöfs Kolben, and Halland native spring wheat.

Numerous controlled experiments confirmed these different degrees of specific resistance the causes of which are not yet known. There is no relation between earliness and the intensity of the attack. The early varieties 0880 (ripe on August 31) and the Halland wheat (August 31), suffered as much as the late varieties 0201 (September 4) and 0804 *b* (September 9). The different behaviour of the varieties may depend on the structure of the flower or the presence of substances toxic to *Fusarium*.

1298 — **Disease-Resistant Sugar Canes, in Porto-Rico.** — See No. 1239 of this Review.

1299 — **Direct Bearers Resistant to Diseases and Pests, in France.** — See No. 1250 of this Review.

1300 — **The Influence of Pruning on the Resistance of Grafted Vines to Diseases and Pests.** — See No. 1231 of this Review.

1301 — **Copper Sulphate and Copper Products in Italy.** — See No. 1210 of this Review.

1302 — **Disinfection of Seed against *Pleospora graminea*, Injurious to Barley.** — LUND, J. and KOPPEL RAWN, F., in the *Tidskrift för Plantæavl*, Vol. XXV, Pt. 1, pp. 56-116 + Bibliography of 20 Publications. Copenhagen, 1918.

From 1908 to 1916 numerous investigations have been made in Denmark to determine the best method of disinfecting seed barley against

*Pleospora graminea* ("Stiibeszyge") which does serious damage to barley crops in the north of Europe.

If the necessary precautions are taken the best results are obtained by soaking the seeds in solutions of formaldehyde, copper sulphate and mercuric chloride. If the material is badly affected it is left in 0.2 % of formaldehyde for 6 hours, or 0.5 % of copper sulphate for 4 hours, or 0.1 % of mercuric chloride for 2 hours. If the material is only slightly affected the time of soaking may be reduced by half.

Treatment with hot water may be carried out in three ways :—

a) soaking for five minutes in water heated to 56 or 57°C., the seeds being softened in cold water ;

b) soaking in hot water followed by the drying of the material at high temperatures — 80°C. or more ;

c) simple soaking in hot water followed by drying in the air at normal temperature.

The best results have been obtained with the last method although it is not so satisfactory as mercuric chloride, formaldehyde and copper sulphate. The appended table gives the efficiency of the different remedies by showing the decrease per cent of affected plants and the corresponding increase in the yield in grain and straw.

Treatment	Number of tests	Percentage of infected plants		Decrease in the percentage of plants infected as the result of the treatment	Percentage of increase in the yield of	
		Grains not disinfected	Grains disinfected		seed	culms
Hot water at 56-57°, followed by drying of the seed at high temperature . . . . .	4	15.3	5.3	10.0	8	4
<i>Idem.</i> without drying . . . . .	17	14.7	1.2	13.5	8	6
Hot water at 50-51°, after softening of the seed . . . . .	11	14.9	1.0	13.9	11	6
Soaking in copper sulphate . . . . .	7	18.6	3.2	15.4	13	7
Soaking in formaldehyde . . . . .	8	20.9	3.4	17.5	12	9

If the treatment has no unfavourable influence on the germinating faculty or germinating energy there is for each percentage decrease in the number of plants infected an increase in yield equal to 0.6-0.8 % for seeds and 0.4 % to 0.5 % for stems.

Early sowing in cold soil favours the development of *Pleospora*. If, in this case, later sowing is impossible, disinfection of the seeds becomes more important than ever.

DISEASES  
OF VARIOUS  
CROPS

1304 - *Bagnisiopsis Dioscoreae* n. sp., an Ascomycete Parasite on Yam in South Nigeria. — WAKEFIELD, E. M., in the *Royal Botanic Gardens, Kew, Bulletin of Miscellaneous Information*, No. 6, pp. 199-201 + 4 Figs. London, 1918

In January, 1918, Mr. C. O. FARQUHARSON, Mycologist of the Agricultural Department, Southern Provinces, Nigeria, sent stems of a yam (*Dioscorea*) attacked by a fungus to the Royal Botanic Gardens for identification. The plant attacked was *D. praehensilis* Benth. The fungus, which belongs to the family *Dothideaceae* and is described as new to science under the name of *Bagnisiopsis Dioscoreae*, is undoubtedly parasitic and the disease, although localised, is serious.

The material examined was collected at the beginning of November 1917, in the Okigwi district though the fungus had already been found on *D. praehensilis* in 1911 at Oban, South Nigeria. The parasite attacks the lateral shoots which arise in the axils of normal leaves and causes marked hypertrophy. The internodes are shortened and the leaves dwarfed, and the stem appears much swollen where the elongated black stromata break through its tissues. Frequently numerous stromata occur parallel to one another so that the cortex is almost entirely replaced by fungus tissue.

1305 - *Colletotrichum linicolum* n. sp., Injurious to Flax Seedlings, in Ireland. — PETHYBRIDGE, G. H. and LAFFERTY, H. A., in *The Scientific Proceedings of the Royal Dublin Society*, Vol. XV (New Series), No. 30, pp. 359-384 + 2 Plates. Dublin, August, 1918.

Flax growers in the north of Ireland frequently complain of a disease of the seedlings which they call "yellowing". The attention of the authors was first drawn to this trouble in the early part of the summer of 1916, when diseased plants from farms in Antrim were sent to them for examination. Observations made by one of the authors during the following spring in Antrim and neighbouring counties showed the disease to be common and the cause of considerable damage to the young crop in some cases.

The principle symptoms of the disease are the development of spots on the cotyledonary leaves and lesions on the young stems, which, in many cases, cause the death of the seedling by a process resembling "damping off" (*Pythium de Baryanum*).

A species of *Colletotrichum* was found associated with the disease. This fungus was isolated and grown in pure culture. Infection experiments made with it showed it to be the cause of the disease. To some extent the disease resembles "flax canker", attributed in the United States to *Coll. Lini* Bolley (1910). It resembles more closely a disease of flax in Holland, ascribed by SCHOEVEERS (1915) to a species of *Colletotrichum* which, according to information supplied to the authors by BOLLEY, is the same as the fungus observed by him in America.

Under the name of *Coll. linicolum*, the authors describe the fungus, proved by them to be the specific agent of the disease, as a species new to science. It was found that the mycelium of the fungus hibernates within the cells of the epidermis of the seed-coat and that the disease is transmitted by the seeds. Transmission of the disease may be largely prevented, by deep sowing so that, on germination, the seed-coats remain underground

This, however, is not a practicable method of control. The disinfection of infected seed with formalin and hydrogen peroxide greatly reduced the number of diseased plants but did not completely eliminate the disease. Treating slightly moistened infected seed with a mixture of finely powdered copper sulphate crystals and dry sodium carbonate suppressed the disease entirely.

Flax-seed from Russia, Holland, Canada, and the United States has been found to produce diseased seedlings, and the disease is believed to be widespread all over the world.

1306 - *Phoma destructiva*, a Deuteromycete Injurious to Tomatoes, in Tunis. — GUILLOCHON, L., in the *Bulletin de la Société d'Horticulture de Tunisie*, Year XVI, No. 122, pp. 131-133. Tunis, 1918.

In Tunis in a tomato crop in 1917 and in different gardens in the summer of 1918 a bacterial disease was observed which threatens to become serious if it is not controlled. The first fruits are generally sound, those which form after July being attacked. The disease first attacks the ripe fruit spreading subsequently to the green fruit. The fruit affected is first covered with very distinct spots and finally decomposes, the flesh becoming blackish and deliquescent. The disease is attributed to *Phoma destructiva* (1).

The author recommends the picking and immediate burning of all spotted fruit, whether green or ripe. At harvest time care should be taken not to leave spotted fruit on the ground as insects may visit it and propagate infection.

1307 - *Keithia Chamaecyparissi* n. sp., an Ascomycete Parasitic on the White Cedar *Chamaecyparis thyoides*, in New Jersey, U. S. A. — ADAMS, J. F., in *Torreya*, Vol. XVIII, No. 8, pp. 157-160 + 2 Figs. Lancaster, Pa., 1918.

A description is given of the new species, *Keithia Chamaecyparissi*, found on *Chamaecyparis thyoides*, at Lakehurst, New Jersey, in the summer of 1915 and again on June 14, 1916. The infected leaves turn brown and apothecia develop on the upper surface of the leaves as circular or elongated pustules. Infection is usually confined to the lateral leaves. On most of the dead terminal leaves *Lophodermium juniperinum* Fr., which appears more prevalent and perhaps more injurious than *K. Chamaecyparissi*, was found. It is probable that, under more favourable conditions, both these fungi may cause serious damage.

## INJURIOUS INSECTS AND OTHER LOWER ANIMALS.

1308 - The Coccidiidae *Pulvinaria platensis* n. sp., *P. flavescens* n. sp., and *P. minuta* n. sp., and their Natural Enemies, in Argentina. — CARIDE MASSINI, P. and BRÉTHES, J., in *Anales de la Sociedad Rural Argentina*, Year, LIII, Vol. LII, pp. 148-158 + 10 Figs. + 8 Plates. Buenos Aires, 1918.

GENERAL

The following coccidiidae of the Argentine are described:—

1) *Pulvinaria platensis* Bréthes n. sp., living on *Eugenia* sp.;

(1) See R. July, 1915, No. 759. (Ed.)

[1305-1308]

2) *P. flavescens* Bréthes n. sp., living on lemon tree ;

3) *P. minuta* Bréthes n. sp., living on *Schinus dependens*.

These three coccididae have not done serious damage so far because, according to the authors, their spread is prevented by the following natural enemies, which are also described :—

1) *Tetrastichus caridei* Bréthes n. sp. ;

2) *Aphicus flavidulus* Bréthes var. *caridei* Bréthes n. var. ;

3) *A. flavidulus* var. *nigra* Bréthes n. var. ;

4) *Onophilus caridei* Bréthes n. gen. and n. sp. ;

5) *Pseudaphelinus caridei* Bréthes n. gen. and n. sp. ;

The most efficient natural enemy of the three coccididae appears to be *O. Caridei*.

1309 - The Origin of the Pink Bollworm (*Pectinophora gossypiella*), Injurious to Cotton (1). — MARLATT, C. L., in *Science*, New Series, Vol. XLVIII, No. 1239, pp. 309-312. Lancaster, La., September 7, 1918.

The determination of the original habitat of the pink bollworm (*Pectinophora gossypiella* Saunders) is of great interest in relation to the present distribution of this insect and may be of importance later as indicating where parasitic or other natural checks may be found.

A scrutiny of the records gives strong support to the theory that this insect originated in Southern Asia, probably India. This is in opposition to the theory of J. H. DURRANT (1912) who asserts that the microlepidopteron may be of American or Egyptian origin, as well as to that of A. BUSCK (1917) (2), who considers that the original habitat of the insect is Africa.

1310 - The Fennec Fox (*Canis zerda*), Useful for Destroying Injurious Insects. — See No. 1266 of this *Review*.

MEANS  
OF  
CONTROL

1311 - Control of Locusts in Capitanata in 1917. — PAOLI, G., in the *Bollettino dei Ministeri per l'Agricoltura e per l'Industria, il Commercio e il Lavoro*, Year XVI (1917), Vol. II, Ser. B., Pt. 5-6, pp. 1-5 of Reprint + 1 map. Rome, 1918.

This paper is a report of the measures taken against locusts in the province of Foggia in 1917, under the direction of the author, Control Commissioner in the Capitanata. As the information supplied by the inhabitants was both insufficient and unreliable, thus making it impossible to establish the localities in which the locusts had laid their eggs the year before (1916), the plan of collecting the egg-nests had to be given up and preparations made to destroy the locusts as soon as they hatched. The locusts occurred in the communes of Foggia (*Deciostaurus maroccanus*), of Ascoli Satriano (*D. maroccanus*) and Castelnuovo della Daunia (particularly *Calliptamus*, *Edipoda* and *Stenobothrus* ; no *D. maroccanus*). The insects were most numerous in the first of these communes, propagating even in the neighbouring communes of Lucera and Troia. Hatching was

(1) See R., Sept., 1907, No. 879 ; R., Aug., 1908, No. 865. — (2) See R. Sept., 1917, No. 879 (Ed.)

first reported on May 5 and 11 from the communes of Foggia and Ascoli Satriano.

In the commune of Foggia action was taken immediately, sprayings with 5 % cresosol emulsion in water being increased to 6, 7 and 7.50 % as the insects grew older. At the same time women caught the locusts in cloths. When the cresosol supply ran out sprayings were made with 1, 2 or 3 % sodium arsenite according to circumstances. On account of the enormous number of locusts everywhere it was not possible to spray in all the places necessary because water could not always be found at a convenient distance, and the amount for each band of workers had to be carefully calculated; it was also sometimes impossible to form further bands of workers. As an experiment it was, therefore, proposed to spread bran moistened with 3% dry weight sodium arsenite on the infected soil. The result was absolutely astonishing.

On the whole little damage was done in the commune of Foggia by locusts in the pupal stage. Only a few ears of wheat, low and badly developed, were eaten and cut. In some places large numbers of the insects attached themselves to culms, thus bending them and causing part of the crop to lodge, but without doing harm. Oats suffered most, the locusts gnawing the peduncles at the base of the spikes and causing the caryopses to fall. In a vineyard, the vines of one plot were completely stripped of their leaves.

In spite of the numbers killed by these precautions the locusts continued to increase and reached the adult stage. Spraying with arsenite of soda and the use of poisoned bran were continued for some time. On June 23, when the insects took their flight, the work was stopped. Immense winged clouds fell with great voracity on the vines and other plants — the cereals were already harvested and shocked — and some vineyards suffered severely though the area damaged was limited. The damage is caused by the locusts' eating the petiole, and causing the leaves to fall. In this way vines, olive, almond, fig and wild pear trees, etc., were stripped of their leaves.

In the commune of Foggia laying began about 48 days after the first eggs hatched. An observation service was then begun to note exactly where the eggs were laid. In spite of the millions of locusts destroyed by the various methods of control an enormous number laid their eggs everywhere. According to data collected in the commune of Foggia the total area over which eggs were laid was 2224 acres; in one locality (Posta Corona) nearly 2 400 nests were found in 1 sq. yard.

In the Ascoli Satriano district, where there were not very many locusts, control measures were carried out from May 13 to June 9 with cresosol and sodium arsenite sprayings and cloths. The locusts may be said to have been completely destroyed there.

In the commune of Castelnuovo della Daunia spraying with sodium arsenite was carried out from June 27 to July 5 on a small scale only because of the few locusts.

The results of the author's 1917 experiments show that cloths are of use when the locusts are young and few in number or to prevent their en-

tering a kitchen garden or other small crop, but are absolutely inefficient against large attacks. Cresosol is much more satisfactory if used by capable workmen, otherwise the locusts escape before the mixture reaches them. Cresosol, like all other insecticides with a basis of tar oil, petroleum, etc., spoils the rubber tubing and internal rubber pieces of the pumps. During the experiments no waxed tubes were available and even the leather of pumps with leather pistons was acted on by the tar. Sodium arsenite is more easy to use when attempts are not made to reach the insects directly but to soak with poison the grass on which they feed. The pumps are not destroyed more than normally and the work is easier and does not require special skill. Continual use of arsenite, however, causes burns and inflammations not easy to avoid. Both with cresosol emulsion and sodium arsenite solution abundant water and labour are required, which are not always available locally.

The use of bran or a similar poisoned substance removes many difficulties and gives excellent results. This is the method which should be most generally adopted after as many egg-nests as possible have been destroyed either by collecting them or by superficial turning of the soil so as to destroy as many eggs as possible before they hatch.

The reasons in favour of poisoned bran are :—

1) it may be prepared in one centre, in the present case, Foggia ; it would be useful to investigate the possibility of preparing it mechanically instead of by hand, as was done in 1917, by using a kneading machine, olive mill, or similar apparatus, taking of course, all due precautions ; this would save part of the labour ;

2) no special skill is required to apply it, it is done by hand, but could be done by machine, with a sieve or a manure spreader ; further labour would thus be saved ; the farmers themselves could take the poisoned bran direct from the store and spread it over their land or round threatened crops, thus decreasing the expenses ;

3) mechanical preparation would eliminate the troubles produced on the workmen's bodies by the prolonged use of sodium arsenite.

INSECTS, ETC.  
INJURIOUS  
TO VARIOUS  
CROPS

1312 — Influence of the Date of Earing on Damage Done to Spring Wheat by the Dip-  
teron *Contarinia tritici*, in Sweden. — ÅKERMAN, Å., in *Sveriges Utsädesfor-  
nings Tidskrift*, Year XXVIII, Pt. 2, pp. 90-93. Malmö, 1918.

During the summer of 1917 larvae of *Contarinia tritici* (" Vetemyggan ") caused considerable damage to spring wheat in Sweden by the destruction of a large number of the flowers. An examination of abundant material showed different varieties of wheats to behave differently.

VARIETIES SUFFERING MOST : — 0821 (of Varpal × Svalöfs Kolben), Svalöfs Kolben, Marquis, 0880 (of Svalöfs Kolben × Dala), Dala, and Halland wheat. In all these varieties the date of the beginning of earing coincides with the moment when most of the female insects are about to lay.

VARIETIES SUFFERING LEAST : — 0804 and 0805 (of 0201 × Värpär), 0810 (of Brunt Schlanstedter × Värpär), and 0850 (of Sol. × Svalöfs Kolben).

All these varieties ear later than the preceding ones, when there are far fewer female insects.

To estimate the extent of the damage several ears of different varieties chosen haphazard here and there were examined. Of a total of 61 145 flowers 3360 (5 %) were destroyed. Considering the average yield to be 15.93 cwt. per acre, the loss due to *C. tritici* is approximately 90 lb. per acre.

**1313 - *Cicadula sexnotata*, a Hemipteron Injurious to Wheat, Oats and Barley, in Sweden.** — ELLINGER, T., in *Vort Landbrug*, Year XXXVII, No. 40, pp. 453-454. Copenhagen, 1908.

During the summer of 1918 *Cicadula sexnotata* ("Dvaergcikade") caused serious damage to wheat in the province of Östergötland and spread in Southern Sweden as far as Scania where, however, its attacks were not serious.

The females lay their eggs on the seedling plants and so alter their growth that they sometimes completely prevent seed-formation. The parasite can pass from winter wheat to spring-sown oats and barley, causing similar injury. The damage caused is related to the variety of wheat or other cereal, to the dates of sowing and emergence of the young plants.

The local wheat and the selected variety "Pudel" are highly resistant. The variety "Thule", obtained by NILSSON-EHLE by crossing the local wheat and Pudel, is also distinguished by its resistance.

Early sowing at the beginning of September causes the phase when the young plants emerge to coincide with the moment when the female insects are most numerous. This coincidence is avoided when sowing, owing to rain or other reasons, is retarded and the intensity of the attack is then much diminished.

**1314 - Mite Disease of Potato, in Hawaii.** — CARPENTER, C. W., in *Phytopathology*, Vol. VIII, No. 6, pp. 286-287 + 1 Plate. Baltimore, Md., June, 1918.

A new potato disease was observed for the first time in May, 1917, near Honolulu and Castner, Island of Oahu. It was subsequently found to be present and destructive in all the potato-growing districts of the Islands and is now considered of great importance. When there is a minimum rainfall, whether the plants be irrigated or not, they frequently dry up and die from the growing tip downwards. The small young leaves, both terminal and axillary, become bronzed on the lower surface, twist and curl upon the longer axis. Both the leaves and shoots become abnormally hirsute, dry up, and die. Often the plants grow well until about the time of flowering before being attacked. The yield of the diseased plants is naturally negligible.

Young parts of diseased plants examined with a hand lens were found to be covered with myriads of tiny mites, as yet undetermined, but probably belonging to the family *Tetranychidae*. It is to this insect that the disease must be attributed.

Tomato plants growing under the same climatic conditions were also attacked by a mite which appears similar to that attacking potatoes. It

has not yet been determined whether this disease is as serious in the tomato as in the potato.

When potato crops are attacked by the mite only, experiments have shown good results to be obtained by spraying with lime sulphur, or dusting with dry sulphur. It is advisable to plant lowland crops in autumn or winter so that they may ripen before the dry season begins.

**1315 - *Gelechia ocellata*, a Microlepidopteron Injurious to the Beet, New for Italy.** — DEL GUERCIO, G., in *L'Agricoltura Coloniale*, Year XII, 1st. Half-Year, No. 4, pp. 216-230 + 5 Figs. Florence, 1908.

Description of the life history of *Gelechia ocellata* Bois., followed by preliminary notes on its biology.

This microlepidopteron was recorded for the first time in Italy by the author during the summer of 1917 in the lower Valdarno, near Florence, and was noted to be a pest of the beet. In July, the freshly-hatched larvae begin to feed on the most tender leaves of the beet. It soon reaches the root by tunneling and finally leaves the plant and completes its life cycle.

Owing to the attack of the insect, the beet foliage withers while the development of the root is more or less stopped.

The larvae of the pest sometimes contain those of an endophagous dipteran, probably belonging to the genus *Masicera*. Various means of control have been tried and arsenical solutions seem to promise good results in the control of the larvae of *Gelechia*. At the same time they help to control a fungus (*Cercospora beticola*) and some coleoptera (*Cassida*) which, in Tuscany and other regions, seriously damage the beet.

## INJURIOUS VERTEBRATES.

**1316 - The Preparation of Active Virus Against Field Mice and Method of Applying it in Fields Infested by these Rodents.** — MORI, N., in the *Annali della Stazione sperimentale per le malattie del bestiame*, Vol. IV (1917), [abstract], pp. 1-22. Naples, 1918.

Of the various methods of controlling field mice that which, since LÖFFLER's experiments in Greece (1893) and DANYSZ's in France (1903), has proved most efficient is the application of pathogenic bacteria in the fields with the aim of causing epizootics among the rodents.

LÖFFLER used *Bacillus typhi murium*, isolated from an infectious disease which broke out among the white rats of his laboratory. DANYSZ used a bacterium isolated during a natural epizooty among field mice and known to be also pathogenic to rats. Other workers subsequently studied bacteria related to those isolated by LÖFFLER and DANYSZ. They may all be considered as belonging to the *B. enteriditis* Gärtner group, according to the classification of LEHMANN and NEUMANN. The most important of them — used in infested fields as well as to destroy rats as a preventative measure against bubonic plague — are:—

*B. typhi spermophilorum*, isolated by MERESHKOWSKY during an epizooty among *Spermophilus musicus* ;

LASER's bacillus, from *Mus agrarius* Pallas ;

ISSATSCHENKO's bacillus, isolated during an epizooty among white rats ;

TRAUTMANN's bacillus, causing a fatal infectious disease among grey rats ;

NEUMANN's bacillus, known to be very pathogenic to rats ; isolated from the urine of a child suffering from cystitis ;

*B. septicaemiae murium* Grimm, pathogenic to rats.

Other workers have isolated other bacteria of this group which have been put on the market under more or less appropriate names. In 1916 SPLENDORE isolated from field mice in Apulia a bacterium which he stated to be the cause of a fatal epizooty (1).

The same year the author also observed a natural infection of field mice caused by *Bacterium murisepticum* (Flügge) Mig. (2).

At Foggia the author made laboratory experiments on field mice (*Pitymys savii* and *Apodemus sylvaticus dichrurus*) with a view to using them ventually in infested fields, with two bacteria of the *B. enteritidis* group — *B. caticida* Mori, the agent of an epizooty of cats studied in 1903, and *B. enteritidis bubalorum* Mori, isolated in 1903 from buffaloes. The results obtained were not very different from those obtained with other bacteria of the same group.

The author further studied the results obtained with haemorrhagic septicaemia bacteria and obtained very good laboratory results with *B. bubalisepticus*, *B. bovissepticus*, *B. suissepticus* and *B. avissepticus*. Good field results were also obtained with *B. suissepticus*.

There is much difference in opinion as to the efficacy of virus in controlling field mice and preventing the spreading of plague by rats. Failure must not always be ascribed solely to the kind of virus used, to the more or less rational method of preparing it, the preservation of its virulence or the method of applying it in the fields. In preparing active virus against rodents choice must be made of the bacterium best suited to the purpose unless a microorganism causing a natural epizooty among the rodents to be controlled and possessing the necessary virulence has recently been isolated. The bacterium isolated must be made virulent to the species against which it is to be used by keeping the experimental animals under conditions as natural as possible, as captivity, by weakening them, may influence the results. When a good virus has been obtained it should be kept so that its virulence will neither disappear nor decrease. It must be applied to the fields rationally. To do this it is necessary to know, not only the biology of the infesting bacterium, but also that of the field mice which has hitherto been too neglected. The virus must be applied to the fields at a suitable period and hour in order to give the best results.

The author then studies the choice of bacterium, the keeping of mice

(1) See R. Sept., 1916, No. 1056; R., April, 1917, No. 396. (Ed.)

(2) See R., Oct., 1918, No. 1187. (Ed.)

in the laboratory for the preparation of the virus, the preparation of the virus, the preservation of the virulence of the bacterium in the laboratory, the choice of media in which to distribute virus to those requiring it, and the method of applying the virus in mice-infested fields.

1317 — Susceptibility of Field Mice in Apulia to Certain Microorganisms Used to Control these Rodents in the Fields. — MORI, N., in the *Annali della Stazione sperimentale per le malattie infettive del bestiame*, Vol. IV (1917), pp. 3-51 of reprint. Naples, 1918.

The experiments made by the author in Apulia in 1910 showed that field mice (*Pitymys savii* and *Apodemus sylvaticus dichrurus*) are susceptible to all the bacteria tested, i. e., those of the *Bacillus enteritidis* group, according to the classification of LEHMANN and NEUMANN, *B. typhi murium* (Löffler, Benn stock), *B. typhi murium* (Danysz stock), *B. typhi spermophilorum* (Merezhkowsky stock), *B. caticida* (Mori), *B. enteritidis bubulorum* (Mori) and, of the hemorrhagic septicemia group, *B. bubalisepticus* (Oreste and Armanni), *B. bovissepticus* (Galtier, Lignières), *B. suissepticus* (Löffler), *B. avisepticus* (Perroncito, Pasteur). These bacteria cause the death of the rodents if administered endothoracically, endoperitoneally or subcutaneously.

Even if these bacteria are previously activated by subcutaneous, endothoracic or endoperitoneal passage they do not cause the death of the rodents if the cultures are administered by the digestive tract. If, however, the gastric juice be first neutralised, the same cultures may prove fatal to 100 % of the animals to which they are administered either directly or in their food. After a first passage through the digestive tract, the gastric juice having been previously neutralised, the bacteria re-isolated from the heart and grown in broth are fatal to 100 % of the rodents whether administered by the same method or without any previous treatment. Successive passages through the digestive tract may so weaken the bacteria as to render them inactive.

Experiments with *B. typhi murium* showed that six passages through the peritoneum of *Pitymys savii* sufficed to make the bacteria inoculated through the peritoneum lose their virulence, whereas seven passages through *Apodemus sylvaticus* greatly activated it. Alternate peritoneal inoculations of the two animals gave, after four passages, a virus very active to both, killing 100 % of caged rodents when administered through the digestive tract. The ingestion of infected carrion caused death more rapidly than ingestion of virulent cultures. Field mice may infect other rodents if kept together with them.

All the bacteria examined, no matter by which method they are introduced into the mice, may be re-isolated pure from the heart if the *post mortem* is made soon after death. A period of 4 to 10 days elapses between the administration by ingestion of bacteria of the *B. enteritidis* group accustomed to infect by this method, and death. The virus from the Danysz stock has the most rapid effect (4 to 5 days). In the case of bacteria of the hemorrhagic septicemia group tested the period between infection and death varied from about 15 to 36 hours.

1318 - The Biological Control of Field Mice (1). — SPLENDORE, A., in *Bollettino del Ministero per l'Agricoltura*, Series B, pp. 1-10 of reprint. Rome, 1918.

By order of the Ministry of Agriculture the author has made since 1916 a study of diseases of field mice and, incidentally, of related forms, with the aim of using natural diseases of these rodents in controlling them. He found that these animals are naturally subject to various diseases. Amongst these must be mentioned first of all those caused by certain bacteria new to science:—

1) *Bacterium pitymysi*, found in *Pitymys savii* from the Contessa district, near Cerignola, province of Foggia.

2) *Bact. pitymysi II*, in individuals of the same rodent from different localities in Apulia;

3) *Bact. pitymysi III*, in *P. savii* from Torremaggiore, Foggia.

4) *Bact. pitymysi IV*, in individuals of the same rodent from the same locality.

5) *Bact. muris*, in two specimens of *Mus sylvaticus* from the Cerignola district.

6) *Bact. microti*, isolated from *Microtus arvalis* sent from different districts of the Carso.

7) A bacterium which appears to belong to the family *Bacillus typhi murium* Löffler, found in white rats bought at Rome.

Amongst the diseases of non-bacterial origin found in *P. savii* from the Capitanata are:—

1) An ERUPTION behind the ears causing the skin to peel easily, believed by the author to be the disease commonly known as "rusa"; no specific bacterial agent was found.

2) ECTOPARASITES:— fleas probably belonging to the genera *Ceratophyllus*, *Typhlopsylla*, and *Hystrichopsylla*; lice, which may be placed in the genus *Haemotopinus*, are continually found in large numbers on field mice; a mite of the family *Gamasidae*, rare on adult field mice.

3) WORMS, including certain cestodes of the genus *Hymenolepis*, frequently found in the small intestines of the rodents. Other cestodes have been found in the larval state in the sub-cutaneous tissue, the pleural cavity, the peritoneal cavity and the parenchyma of the liver, in *P. savii*. With the exception of a single specimen of acanthocephalus (*Gigantorhynchus moniliformis*?) in the small intestine of one *P. savii*, only a very small nematohelminth (*Oxyuris*?) was found in the caecum of field mice, and this only in a very few cases.

4) PROTOZOA: a *Hexamitus* near the duodenum; a *Megastoma* throughout the small intestine; a *Trichomonas* in the large intestine; a haemogregarine is sometimes found, the schizogony of which occurs mostly in the lungs, which the author believes represents a species new to science, called by him *Hepatozoon pitymysi*; in three cases was found a sarcosporidium

(1) See R. Sept., 1916, No. 1050; R. April, 1917, No. 396; R. Oct., 1918, No. 1187. (Ed.)

believed by the author to be a species new to science called temporarily *Sarcocystis pitymysi*.

5) FUNGI. In a group of *P. savii* from the province of Salerno the author observed a disease, usually in the respiratory organs, which was undoubtedly caused by parasitic fungi. The cultural experiments made so far have shown the presence of an *Aspergillus* frequently accompanied by a *Penicillium*.

Of all the the diseases mentioned those caused by bacteria are the most likely to produce spontaneous epidemics in field mice. These spontaneous diseases are not rare, and if it be considered that they are fatal and sometimes epizootic — they are contagious and may be transmitted by fleas — the disappearance of field mice so often observed when they occur in large numbers, may be attributed to them as the conditions for spreading contagious diseases are then most favourable.

The best method of spreading these diseases is to send out field mice infected with the virus by sub-cutaneous inoculation. This system is similar to that occurring in nature and is usually certain to succeed. Virus from naturally infected mice is preferable to that obtained artificially by laboratory cultures because, as a rule, the material from natural infection is more virulent than that obtained experimentally.

It is not rare to find in fields, mice which have died naturally. Apart from a microscopic examination, it is easy to determine whether death is due to one of the above-mentioned bacterial infections for, should this be so, the spleen is large and brown. To obtain infected material for use it is sufficient to collect, with the necessary care, the spleen or liver of dead mice and use them while they are still in a good state of preservation. To prepare the inoculations the material is separated with sterilised pincers in salt water (0.80%) which has been previously boiled and cooled. Two drops of the emulsion thus obtained are inoculated into each mouse, which is then let loose in the field to carry the infection. This method is perfectly harmless to man and all useful animals and may be carried out by any careful person, even the farmers themselves, though it is best that it should be controlled and directed by a bacteriologist. In the absence of naturally infected material animals infected in the laboratory might be used.

The disease could be spread by introducing infected mice into a freshly-dug hole in the field. It is not necessary to do this in all the newly-dug holes of the district as infection within a limited area is sufficient. As the infection increases these areas become centres from which the disease spreads over the whole district infected. A few days after the infected mice have been let loose careful observations are made to see if there are still many rodents. If so a second lot of mice are affected with fresh virus to make success more probable.

Infected field mice give better results than infected material. Inoculated mice set free in newly-dug holes will certainly come in contact with other mice and infect them, whereas it is never certain that material placed on the ground will be found and eaten by the mice, especially if plants and other food are plentiful at the time. This system is also economical, requiring

neither a large outfit nor a large staff. If the virus is obtained it is only necessary to catch the mice, and this may easily be done by means of traps.

It may be assumed that during winter conditions are not very favourable to propagation. Fleas are rare on the mice which themselves are scattered, living in families, more or less far from each other, and rarely leaving their holes, living on stocks collected in summer. In this case it is best to introduce the disease directly into each family, either by introducing an inoculated field mouse or by placing a few grains of oats soaked in bacterial cultures into each hole.

GENERAL INFORMATION.

1319 — *An Agricultural Journey through the Belgian Congo.* — LEPLAE, E., *Ministère des Colonies de Belgique, Direction de l'Agriculture*, 44 pp. + 32 Photographs. London, 1918.

DEVELOPMENT  
OF  
AGRICULTURE  
IN DIFFERENT  
COUNTRIES

Since being taken again by Belgium in 1908, the Belgian Congo has developed to an astonishing extent. Not even the war could stop its economic progress. Twenty years ago the Colony was considered an unhealthy country with limited resources which Belgium could only administer and civilise at great expense, without any hope of a good economic future. Since Belgians have learnt to appreciate better its climate, agricultural and mineral wealth, the inherent qualities of the natives and the value of its immense network of rivers, this colony has been looked upon as a rich, healthy country, essential to the reconstruction of the industrial and commercial property of Belgium.

Considerable progress in agriculture has been made of recent years. Native agriculture is being rapidly developed. Important results have just been obtained in the growing of rice, oil palms and cotton. The natives are good farmers and the State sees that they reap the profit from their work. Agriculture in plantations is less advanced. There are, it is true, some large plantations belonging to societies, missions, or the State, rarely to private owners, but they increase in number very slowly and, up till now, Belgians do not appear to have given them the attention they deserve. Nevertheless, the private and State plantations have shown that tropical crops will enable active and persevering planters to make themselves an independent position in a few years.

The little interest taken by Belgians in colonial agriculture seems chiefly due to the fact that this agriculture is little known in Belgium, perhaps also in part to the bad reputation of the Congo climate and the failure of certain agricultural undertakings of the State and plantation societies. The first difficulty is about to be solved by a decision of M. RENKIN, Minister for the Colonies, which annually allows several Belgians who may wish to settle as planters in the colony, to acquire the necessary practical knowledge at very little cost. They may be admitted as students into the plantations and breeding-stations of the Congo State and, during one year, study all the cultural and administrative work. Their number is of necessity limited and fixed in advance (only 20 in 1918). They are engaged by contract as overseers. The State pays almost all their travelling expenses, gives them 10 frs. (8s.) a day, and supplies them with a native servant and the workmen required to clear and plant a kitchen garden. The second difficulty, that of the climate, is already solved. Since Europeans find in the Congo all necessities and have learnt to protect themselves against the common diseases of hot climates, their health does not suffer in any way. The third point, the failure of the State agricultural undertakings and of certain plantation societies, no longer exists in view of the results obtained at the present time. The plantations are some years old and many are bearing (most are composed of trees which bear only when 6 to 8 years old). Experience gained during 10 years at the cost of many failures has made it possible to improve greatly the general position and the agriculturists have obtained a good knowledge of the agricultural conditions of the colony.

The Minister for the Colonies has, since January 1, 1918, placed six plantations of the State under special control. Henceforth they will be exploited commercially, as also will be the private estates. The financial results will be published annually in an appendix to the general Budget of the Colony. The aim of this is to show the public the cost and profit to the Congo of the principal colonial crops (cacao, rubber, coffee, cotton, palm, etc.). The stations which come under this new control are those of Ganda Sundi (Mayumba), Bakusu (Equator), Barmubu and Yangambi-N'Gazi (Aruwini), Lula and Avakubi (Stanleyville), and Nyangwe (Maneima). The last two are not yet ready but soon will be.

*Meteorological service.* — A meteorological service has been organised since 1911 by the service of Agriculture. Three first-class stations have been formed — Banane, Eala and Elisabethville. Second and third class stations have been established in the State plantations and a certain number of mission centres. The Elisabethville Station, fitted up with numerous recording apparatuses and a seismograph for registering earthquakes is unique in Central Africa, both for its equipment and its position. Besides the stations under the control of the Agricultural Service, meteorological observations are made at the wireless telegraph stations. Several other observation posts were organised five years ago to help aviation.

The agricultural necessity of meteorological observations was not recognised in the colony for a long time. The difficulties met with in cotton-growing at the beginning were due above all to insufficient knowledge of

the climate. Astonishing phenomena are sometimes recorded. For example, on June 8, 1916 a temperature of 39° C. at midday was recorded in the table-land in front of the Katentania, Katanga, Station, and — 4° C. at 3 o'clock in the morning in the valley over 1300 ft. below, the difference in temperature being 43° C. Moreover, frost is frequent in the grassy valleys of Katanga in the dry season and makes wheat-growing difficult.

*Experiment stations.* — The State agricultural and breeding stations and plantations are described (1), and a summary given of the experiments made by the Agricultural Department in each. The most important private estates are also mentioned.

*State agricultural stations.*

(The stations marked with an asterisk have been wound up or sold to favour recolonisation).

1320 - *Tsetse Flies and Fly-Belts, in Africa.* — CHRISTY, C. (Major, R. A. M. C.), in the *Annals of Tropical Medicine and Parasitology*, Vol. XI, No. 3, pp. 279-282. Liverpool, January, 31, 1918.\*

A "fly-belt" is not a region where species of *Glossina* belonging to the *morsitans* group can always be found, but a district beyond which the fly is rarely to be met with. It is known that the fly migrates *en masse* from one part of the belt to another within certain limits, a fact that, so far, has not been explained rationally; when flies follow animals or men they leave

(1) The most important have already been described in the original article by M. F. FALLON; see R. Feb., 1917, pp. 177-185. (Ed.)

them as soon as they pass the limits of the belt, outside which there is something inimical to the fly which is unknown to us. The author is convinced that animals play a small or no part in the mystery; he has often found the insect in swarms in regions containing extremely few animals, and he has not found it in regions with plenty of wild animals of all kinds.

The author considers it most dangerous to assume that wild animals are the chief reservoir of sleeping sickness, because a trypanosome sometimes found in them cannot be distinguished microscopically from the trypanosome known to cause the disease in man. The author thinks that the animals to be implicated in the transmission are pigs (wild and especially domesticated) and, in 1914, together with Dr. DUTTON, he noted (*Reports of the Liverpool School of Tropical Medicine, Sleeping Sickness Expedition to the Congo*) that *Glossina palpalis* was frequently seen in the ears of the pigs, often being thus carried considerable distances from the water. The author, wishing to obtain positive evidence for or against the theory, that wild animals were an important reservoir for sleeping sickness, has examined microscopically (as soon after death as possible) the blood of numerous animals. Out of 100 animals, including the giraffe, elephant, buffalo, dinker, pig, colobus monkey, etc., only five were found to have trypanosomes in their blood, and only one, a wart-hog, out of all the number, had a species of trypanosome which might be mistaken for the human trypanosome. Many samples of buffalo blood were examined, but on no occasion were any trypanosomes found in them.

1321 - **Utilisation of the Serum of the Horse for Human Nutrition.**—LINET, L., in the *Comptes rendus des Séances de l'Académie d'Agriculture de France*, Vol. IV, No. 29, pp. 807-810. Paris, October 2, 1918.

It has occurred to M. CESARI ("Vétérinaire-major") that, in war time when no part of an animal fit for food should be neglected, there would be no objection to the substitution of albumin from horse's blood for white of egg in cooking. The blood of the horse contains 8 % of coagulable albumin and white of egg 10 %.

The author describes tests made under the direction of Lieutenant G. LACOUR.

The method followed was to collect the blood under very clean conditions, to extract the fibrin by beating, then leaving to stand to allow the globules to settle. The settling takes place more quickly with blood of the horse than that of the cow, sheep, etc. Settling could be hastened and the serum increased by centrifugalisation.

The author and those present at the tests tasted various dishes in which the serum replaced white of egg (omelettes, rice cake, waffles, etc.) and which were pronounced very good.

The difference in price between horse serum and white of egg is enormous: the blood of a horse fetches about 2*d.*, for which price 20 litres of blood or at least 10 litres of serum are obtained. Supposing that it costs 9 ½*d.* or even 1*s.* 6*d.* with the treatment, even then the 10 litres of serum will replace the whites of 200 eggs; if it is admitted that the white is only one-third the value of the egg, the whites of 200 eggs are worth at least 24*s.*

1322 — On the Appearance of the Antiscorbutic Substance during the Germination of Seeds. — WEILL, E., MOURIQUAND, G. and Mûle, PÉRONNET, in the *Comptes rendus des Séances de la Société de Biologie*, Vol. LXXXI, pp. 607-610. Paris, June 8, 1918.

The authors have found that, contrary to the theories of FURST (1), seeds (oats, barley) during germination (3 days) have no antiscorbutic power whatever as regards the nutrition of the guinea-pig, as such animals fed on germinated seeds showed more intense scorbutic lesions than those fed on dried grains, probably on account of their prolonged survival. This power should appear later, during the development of the plant. Thus, a guinea-pig given a mixture of barley germinated for 3 days and barley germinated for 10 days (grass) showed normal health and growth after 200 days of experiment.

On the contrary, however, these germinated seeds gave the animal a survival that was double, triple or quadruple that given by dried seeds, or reasons most of which remain to be ascertained.

1323 — Organisation of Public Professional Teaching of Agriculture, in France. — I. *Feuille d'Informations du Ministère de l'Agriculture*, Year XXIII, No. 33, pp. 1-3. Paris, August 13, 1918. — II. *Bulletin de la Société des Agriculteurs de France*, pp. 199-200. Paris, August, 1918.

AGRICULTURAL  
EDUCATION

The new French law of August 2, 1918, on the organisation of public professional teaching of agriculture in France, is intended, according to M. VIGER, who presented the law to the Senate, to provide agricultural education no longer for 2000 youths and a few hundred girls, but for 1 million youths and 1 million girls.

1) EDUCATION FOR YOUTHS. — *Agriculture* is taught (art. 1): — 1) at the "Institut national agronomique", which is the normal higher school for agriculture; 2) at the National Schools of Agriculture of Grignon, Montpellier, Rennes; 3) in the schools of agriculture including a) schools of practical agriculture; b) the farm schools; c) the technical schools where some agricultural speciality is taught; 4) in the winter or seasonal schools of agriculture; 5) in the agricultural continuation courses.

*Horticulture* is taught: — 1) at the National Horticultural School at Versailles, which is the higher school for horticulture; 2) in the schools of horticulture as in section c (technical schools).

In order to give a thorough practical training to the pupils leaving the National Agronomic Institute wishing to take up an agricultural career or become professors of agriculture, practical schools will be founded on the estates of the National Schools of Agriculture, at Grignon, Montpellier and Rennes. These schools could also be attended by students from the national schools wishing to specialise and by free auditors (see art. 3 of the law). As regards the *practical schools*, owing to the bad results given by the way of running some of them as actual farms on which the director-farmer, obliged to make the greatest possible profit out of his farm, considers the students as labourers, in many cases, rather than real pupils.

(1) FURST. — *Zeitschrift für Hygiene and Infektionskrankheiten*, 1912, LXXII, p. 122. (Authors' note).

the law provides that save in exceptional circumstances the farm shall be run either on behalf of a commune, a department, or the State (art. 10).

The really new part of this law is that tending to create and spread everywhere in France the winter or seasonal agricultural schools and public continuation agricultural education.

Art 14 — The *winter or seasonal agricultural schools* are fixed or travelling. They are designed to give, during the bad season, professional instruction to the sons of farmers who cannot spend 2 or 3 years in a professional school of agriculture. They are controlled by the Minister for Agriculture.

According to art. 20, *continuation agricultural instruction* can be given in public schools or in premises placed at the disposal of the State by the communes or private persons. In each commune, the course is started either on request of the municipal council, or on request of the departmental commission provided for in art. 23, and on a favourable report from the general Council. The course, according to art. 22. of the law, is paid for by the department.

II). EDUCATION FOR GIRLS. — Art. 26 — Instruction in agriculture and housewifery for girls is given :—

1) at the National Agronomic Institute ; 2) in the National Schools of Agriculture ; 3) in the agricultural housewifery schools, which may be fixed, temporarily fixed or temporarily travelling and which will be known as "*Ecoles agricoles ménagères*", "*Ecoles agricoles ménagères temporaires*", and "*Ecoles agricoles ménagères ambulantes*" ; 4) in the course of continuation instruction in agricultural housewifery.

The conditions under which the new law is to be applied will be fixed by the rules of public administration.

#### AGRICULTURAL INSTITUTIONS

1324 — High Council of Agricultural Stations and Laboratories, in France. — *Journal Officiel de la République Française*, Year L., No. 222, p. 7280. Paris, August 16-17, 1918.

An order of the Minister of Agriculture, dated August 12, 1918, constituted a High Council of Agricultural Stations and Laboratories composed of 25 members, 9 of which are elected by the "*Académie des Sciences*", 6 by the High Council from competent persons of note, and finally 4, representing the Minister of Agriculture, are named by him. The members are appointed for 3 years and one-third will be re-elected each year; they are eligible for reelection. The General Inspector of Agricultural Laboratories will be present at the meetings for purposes of consultation. The Council has to watch over the working of the agricultural Stations and Laboratories, to guide and direct them in the path assigned to them so as to make them as highly useful as is possible. It treats with all questions relating to scientific researches to be undertaken and to be carried on in those establishments.

#### EXPERIMENTAL AND ANALYTICAL WORK

1325 — Recent Investigations at the Imperial Institute, London. (1) — *Bulletin of the Imperial Institute*, Vol. XV, No. 4, pp. 465-503, 544-568. London, October-December, 1917.

UTILISATION OF STALKS OF FLAX CULTIVATED FOR SEED. — As a rule

(1) See R. Oct., 1918, No. 1075. (Ed.)

[1322-1325]

the stalks of flax from which the seed has been removed are burnt. This is the best way of utilising small quantities as the ash can be applied as fertiliser. When, however, as in Argentina, the United States, and Canada, flax is grown on a large scale, other possibilities should be considered. At present there are two such possibilities: — 1) production of tow from the stalks; 2) the manufacture of paper pulp or paper. Both these methods demand expensive equipment and can only be adopted where there is a large quantity of raw material and a local market for the final product, which is not sufficiently valuable to export. In Rhodesia the cultivation of flax as an oil-yielding plant is rapidly increasing, and the British South Africa Company sent to the Imperial Institute a sample of flax stalks for information as to the methods of utilising them. The sample contained 11.1 % of moisture and 3.6 % of ash. The fibres extracted were from 12 to 25 mm. long. Treatment with caustic soda gave 44 % of strong paper which did not bleach easily. Treatment with sulphite gave 45 and 46 % of paper which bleached without difficulty. By crushing between rollers, beating and threshing, about 23 % of tow suitable for paper-making was obtained. When treated with caustic soda the tow yielded 50 % of paper but little superior to that obtained from the whole stalks. The shieve when treated with caustic soda gave 43 % of pulp which did not bleach and could only be utilised if mixed with longer-fibred material or for making very common paper.

PRODUCTION OF SISAL HEMP. — Samples from South Africa, British Honduras, and the Belgian Congo gave on analysis the following results:— Moisture, 8.2, 10.1, 9.5 %; percentages on dry fibre basis. — Ash, 1.6, 0.7, 1.1; loss on  $\alpha$ -hydrolysis, 9.3, 11.3, 14.8; loss on  $\beta$ -hydrolysis, 10.8, 13.6, 15.9; loss on acid purification, 1.3, 2.3, 2.2; loss on washing in water, 1.3, 2.6, 2.0; cellulose, 79.2, 76.7, 74.8. The first two were of good quality, the third less so.

FIBRES FROM THE BELGIAN CONGO (1). — Besides the Sisal hemp (*Agave rigida* var. *sisalana*) mentioned above fibre of the following plants was examined:— Bowstring hemp (*Sansevieria cylindrica* and *S. guineensis*), Mauritius hemp (*Furcraea gigantea*), Manila hemp (*Musa textilis*), ramie (*Manniophyton africanum*, *Boehmeria nivea*), and *Arenga saccharifera*. On analysis the first four gave the following percentages respectively: — \* Moisture, 8.5, 9.2, 8.45, 8.5; on dry fibre basis: — Ash, 0.4, 0.9, 0.75, 0.9; loss on  $\alpha$ -hydrolysis, 9.0, 10.4, 11.35, 11.8; loss on  $\beta$ -hydrolysis, 13.0, 13.7, 15.75, 21.0; loss on acid purification, 1.1, 2.0, 1.15, 2.4; loss on washing in water, 1.1, 0.4, 0.9, 1.8; cellulose, 74.0, 76.5, 77.4, 75.0 (the figures for *Furcraea gigantea* are the averages of two samples). Bowstring hemp is obtained from several species of *Sansevieria*, chiefly from *S. Ehrenbergii* of East Africa, *S. guineensis* of West and East Africa and *S. cylindrica*, found from Zanzibar to Angola. The fibre is used for cordage. *Manniophyton africanum* is an Euphorbiaceae confined to tropical West

(1) For other fibres of the Belgian Congo previously examined see R. Feb., 1917, No 1118. (Ed.)

Africa. The bark is utilised by the natives of the Belgian Congo (where the plant is known as "N'kossa") for the extraction of a strong fibre used for making fishing lines. The samples examined were considered suitable only for making strong, but very coarse ropes. By degumming with dilute alkaline solutions a clean, fine, but weak fibre is obtained. *Arenga saccharifera*, or sago palm, is commonly cultivated in India, chiefly as a source of palm wine and sugar, and has been introduced into most tropical countries. From the base of the petiole is obtained a black fibre known as "ejow" or "eju", much used in the East. Three qualities are prepared: — 1) coarse, for brush making, 2) medium, for rope-making, 3) fine, for stuffing cushions and as tinder. The samples from the Belgian Congo were judged of good quality as material for stuffing, brushes, etc.

PRODUCTION OF OIL-YIELDING SEEDS FROM RHODESIA. — The production of oil seeds promises to become an important industry in Rhodesia. The only oil seeds at present produced on a commercial scale are peanuts and sunflower seeds, but experiments made at the Salisbury Agricultural Experiment Station have shown that other oil seeds, including linseed, sesame, niger seed and *Madia sativa* (locally known as Chile Oil seed), may be grown successfully. The cultivation of peanuts is steadily increasing as a result of the introduction of improved varieties by the Department of Agriculture. The exportation of sunflower seeds promises to become important. Peanuts and castor-seeds are grown by the natives in some parts of the country and the oil extracted for local use. Various oil seeds are being grown at the Government Experimental Gardens at Mazabuka and Chilanga, North Rhodesia. Samples of seed sent from these gardens to the Imperial Institute for examination gave the following yields in oil (on a dry seed basis): — Red Zanzibar Castor bean (*Ricinus sanguineus Zanzibaricus*), 51.1 %; black sunflower, whole seed 27.5 %, kernel 49.1 %; striped Russian sunflower, whole seed 21.5 %, kernel 48.8 %; sesame, 53.1 %; white flowering linseed, 34.7 %, Pskoff linseed 35.9 %.

NEW PALM NUT FROM COLOMBIA. — The sample examined at the Imperial Institute was sent from the Tropical Agricultural Station, San Lorenzo, Colombia. Two varieties of the palm are very common in the Magdalena valley, one with large fruit, found in the lower valley, where it is known as "çoroza", one with smaller fruit, found in the higher valley, where it is known as "cuesco". The sample examined belonged to the first variety and appears to belong to *Scheelea excelsa* Karst. (= *Attalea excelsa* Mart.). The fruit consists of two or three nuts in a hard shell. The kernel, which is difficult to remove, contains 4 % of moisture and yields 65.4 % of fat melting at 29° C. In appearance the fat is similar to that of several kinds of palm (palm kernel and coconut oils), but differs from them in chemical characters (low saponification value, 224.6; high iodine value 35.2 %; relatively small quantity of volatile acids, 2.1 % soluble and 3.0 % insoluble). The oil of these nuts is much valued in the tropical parts of Colombia, where it is used for cooking, burning, soap-making, as a lubricant and as a medicine.

WATTLE BARK AND WOOD. — Before the war the British market obtained much tanning material from the Continent; this market being closed,

attention was turned to the large supplies of wattle bark in South Africa, and the manufacture of wattle bark extract was undertaken in South Africa as well as in the United Kingdom; 6 505 tons of the bark were shipped direct from Natal to Russia in 1916. Wattle barks are derived from various species of *Acacia*, indigenous to Australia and introduced into South and East Africa, where they are grown in plantations. The best known as a tanning material in Europe is the bark of the black wattle (*Acacia decurrens* var. *mollissima*). The production of wattle bark is a very important industry in South Africa, especially in Natal, and it is rapidly growing. In 1916, there were about 160 000 acres under wattle in Natal; the exports of chopped bark from South Africa rose to 50 867 tons with an average price of £ 13 10s per ton. The chief sources of the Australian bark are the golden or broad-leaved wattle (*A. pycnantha*) and the black wattle (*A. decurrens* var. *mollissima*). In the East Africa Protectorate there are about 12 000 acres of wattle.

Commercial wattle bark contains an average of 32 % of tannin. Material remaining after being used for tanning or preparing the extract can be used for the production of paper; the wood can be used either for dry distillation or paper making. In experiments made at the Imperial Institute spent wattle bark (containing 11.5 % of moisture, 41.2 % of cellulose and 8.7 % of ash) yielded, according to the treatment, from 28 to 35 % of dry unbleached paper pulp. Commercial tests in a paper works gave from 28 to 30 % of pulp quite suitable for making brown paper.

Wattle wood yields 61 % of cellulose (expressed on the dry material) and gives from 46 to 50 % of pulp which is lacking in strength owing to the shortness of the fibres. The pulp might be used for making "straw-board" especially if mixed with equal parts of spent wattle bark.

THE PRODUCTION OF TURPENTINE OIL AND ROSIN IN INDIA. — Turpentine-yielding trees are common in the forests of the Himalayas, in the United Provinces, in Assam, Burma and the Punjab. The oil and rosin extracted are used locally, but the quantity produced does not suffice. The chief source of Indian rosin is the Chir pine (*Pinus longifolia* Roxb.) which must be distinguished from the American *P. longifolia* Salisb., now usually known as *P. palustris* Miller. The latter is the longleaf pine of the Southern United States, and is the chief source of American turpentine oil and rosin. Five species of pine are indigenous to India: — *P. longifolia* Roxb (Chir pine), occurring in the Outer Himalaya and Swalik Range; *P. excelsa* Wall., (Kail or blue pine), occurring in the temperate Himalayas; *P. Khasya* Royle (dingsa or khasia pine), occurring in the Khasi hills, in Assam and Burma; *P. Merkusii* Jungh. and de Vriese (tinyu pine), of Burma; *P. Gerardiana* Wall. (Neosia or Himalayan edible pine) on the inner dry and arid West Himalayas. *P. longifolia* is the most important species in India for the commercial production of turpentine and rosin, smaller amounts being derived from *P. excelsa* and *P. Khasya*. *P. longifolia* is gregarious over about 2 068 530 acres, but it is tapped only in the Kurmann Division of the United Provinces and in Rawalpindi, Punjab. *P. excelsa* occupies about 65 000 acres in the United Provinces and the Punjab. *P. Kha-*

*syra* occupies an area of 33 sq. miles in Assam. Both in the United Provinces and in the Punjab, the tapping of the trees and the distillation of the oleoresin are conducted by the respective Forest Departments, whilst the sale of the turpentine and rosin is controlled by the manager of the distillery at Bhowali, in the United Provinces. In 1915-1916, in the United Provinces, 981 906 trees were tapped on 49 135 acres, giving 2 089 tons of crude oleoresin; the Bhowali distillery produced 1285 tons of rosin and 80 390 gallons of turpentine. The Indian turpentine oil from *P. longifolia* yields practically no distillate below 165°C., and for this is quite different from American turpentine oil, which should yield not less than 70 % by volume between 155° and 160° C.; it most nearly resembles Russian turpentine oil. *P. longifolia* oil distilled above 175°C contains 25-33 % of *l*-terpene boiling at 173°; the large proportion of this constituent renders the Indian oil inferior to the best French and American turpentine oils, which consist almost wholly of pinene boiling at 156°C. Indian turpentine oil can be used, however, like the other varieties.

**COPAL FROM COLUMBIA.** — The Imperial Institute has examined a sample of copal sent by the Director of the tropical Agriculture Station, San Lorenzo, Colombia. The copal is known locally is "ambara" or "algarovillo" and before the war, was exported to some extent to Germany. The sample submitted was of good quality and has the following characteristics: — moisture, 0.52 %; ash, 0.09 %; melting point, 123°C.; acid value, 100.8; saponification value, 103.6; loss on melting, 18.0 %.

**TOBACCOES FROM NYASALAND AND UGANDA.** — In 1916-17 there were 7 484 acres under tobacco, in Nyasaland, giving an export of 4 304 124 lb., besides quantities stored. Three sets of samples, grown and prepared on the Government Farm at Namiwawa, Nyasaland, and illustrating *a*) the results of topping experiments, *b*) of manuring tests, and *c*) grades of tobacco forwarded to London for sale, were examined by the Imperial Institute.

*a*) The 9 samples of "Gold Leaf" tobacco, topped at different heights so as to mature from 7 to 15 leaves per plant, were very similar; it seems that, on the whole, higher topping, viz., to produce 14 to 15 leaves, is not disadvantageous.

*b*) The 6 samples of "Conqueror" tobacco were manured as follows: — 1) lime; 2) cattle manure; 3) cotton seed; 4) control; 5) lime and cattle manure; 6) lime and cotton seed. The effect of the different methods of manuring was not very marked; certain treatments, especially those with lime + an organic manure, produce a slightly stronger flavour due to the increase in the percentages of lime and nicotine. The burning properties were not noticeably altered by the manuring in any case.

*c*) The tobacco growers of Nyasaland grade their tobacco into two groups: — *a*) mahogany and dark leaves of heavy or good body, suitable for pipe and plug tobacco, and *b*) brighter and thinner leaves suitable for cigarette tobacco. Each group is further divided into commercial grades.

Tobacco is grown on a comparatively small scale in Uganda, mainly by the native for local consumption.

Samples of Virginia tobacco grown and cured on the Nambeya Estate,

Bulemezi, Mengo District, near Kampala, had a good chemical composition (moisture 14.0 % ; nicotine 1.9 % ; nitrogen 2.7 % ; ash 18.7 %) with a low percentage of nitrogen and a large proportion of potash (the ash contained: — lime 26.0 % ; magnesia 9.4 % ; potash 34.6 % ; soda 3.1 % ; sulphuric anhydride 3.0 % ; chlorine 1.9 %).

## CROPS AND CULTIVATION.

1326 — The Question of Hail-rods and Storms in the Gironde, France, in 1918. — ANGOT, A., in the *Comptes rendus de l'Académie d'Agriculture de France*, Vol. IV, No. 30, pp. 838-840. Paris, October 9, 1918.

AGRICULTURAL  
METEOROLOGY

M. ANGOT has presented to the Academy a study, by M. COURTY, astronomer to the Bordeaux Observatory, on the storms observed in 1917 in the Gironde and part of Dordogne, a region furnished with a large number of hail-rods ("niagaras électriques").

In his report, M. COURTY gives a table showing the localities where hail-rods have been installed and the number of times that hail fell in these localities during the 6 years 1911-1917. In two localities the observations ended in 1916 at the same time as the Municipal Council requested the prefect to order the removal of the hail-rod as they blamed it for the frequency with which hail had fallen since the hail-rod had been set up. On the contrary, in two other localities no hail was observed during the six years.

M. COURTY simply gives the facts observed, without drawing conclusions, while expressing the wish that these observations should be continued. In fact, the irregular appearance of hail throws doubt on any conclusions that might be drawn from a small number of observations.

M. ANGOT supports M. COURTY's wish, as the results will be all the more searching as the period of observation is longer. The 5 years of observations made by the author of the study tend to confirm M. ANGOT's previous opinion: that hail-rods have no influence whatever on hail.

1327 — Relation between Climate and Cereal Yield in Sweden. — WALLÉN AXEL, in *Ymer*, Year XXXVIII, Pt. 1, pp. 1-23 + 2 Figs. + 2 Tables + Bibliography of 8 Publications. Stockholm, 1918.

The author has calculated for every province of Sweden the coefficient of correlation,  $r$  (1), between the monthly temperature, monthly rainfall and yield in grain of barley, oats, wheat and rye. Numerous graphs illustrate the figures clearly and maps show the lines of distribution of the values of  $r$  by province, thus making it possible to form a clear idea of the relation between the meteorological factors and agriculture in the different districts of Sweden.

WINTER CEREALS (WHEAT AND RYE). — In the coast districts of southern Sweden (Malmöhus, Kristianstad, Blekinge, Gottland Island, the southern part of Kalmar, Halland) the maximum values of  $r$  with regard to temperature for wheat are: — November — 0.23; May — 0.21; January

(1) See R. Feb., 1918, note to No. 148, p. 175. (Ed.)

+ 0.28; February + 0.26. The summer values for  $r$  are low, but constantly negative. This is certainly due in part to the hot summer of 1901 which was very detrimental to the crops of the south which generally lacked rain.

The coefficient of correlation for precipitation is always very low, except in May, which has very high positive values: — Kalmar + 0.59; Blekinge + 0.52.

A temperate winter, cool and rainy May, and a moderately warm summer are necessary to obtain a good wheat harvest in the coastal districts of South Sweden. About the same conditions are necessary for rye.

As the north and interior of the country (Göteborg, Älvsborg [the part south of Vänern], Jönköping, Kronoberg, the north of Kalmar) are approached the total temperature decreases gradually and the correlation coefficient for the summer months becomes positive, a hot summer being necessary to ensure ripening. For winter, on the other hand, the observations respecting the preceding zone hold good here as well — February + 0.22, March + 0.24, April + 0.23. The gradual lowering of the temperature is accompanied by an increased rainfall which assures the plants the necessary amount of moisture for each stage of their growth. The result is that the relation between yield and precipitation tends to be nil and the values for  $r$  are always very low.

The same conditions exist for rye, though the value for  $r$  expressing correlation between yield in grain and the temperature of November and December is in this case negative. In the provinces of Östergötland, Älvsborg (to the west of Vänern), Sävleborg, and other provinces of Svealand, the lack of heat is still more marked. As a result, except for August and September, the correlation coefficient between temperature and yield for the vegetative period is always positive: — August — 0.39, September — 0.21, November + 0.21, February + 0.26, March and April + 0.25. The values of  $r$  for rainfall are distinctly positive for August, September, April and May (sowing, appearance above ground, earing), and negative for June and July. For rye, unlike wheat, a temperate winter is disastrous. The value  $r$  is markedly negative in January and remains positive in February, but is almost negligible.

In the northern provinces of Jämtland, Västernorrland and Norrbotten, where only rye is grown, the coefficient of correlation of temperature is always positive, except in September, and the maximum values occur in April, May, and July, when they are + 0.41, + 0.44, and + 0.42 respectively. For precipitation the values are: — October + 0.27, June + 0.23, August — 0.48.

The most striking facts deduced from these data are: —

1) The existence of a negative correlation coefficient between yield in grain and the temperature of August and September in northern and central Sweden and some parts of southern Sweden.

2) A negative  $r$  value for the temperature of November and December, especially in South Sweden.

3) A positive relation between the temperature of the winter months

and yield, the value of which decreases as the north is approached until it is reversed and becomes negative (Norrbotten, etc.).

4) The favourable influence of a cool, wet May in South Sweden.

5) In the northern provinces there is a positive correlation with the temperature of the summer months, i. e. the best crops are obtained after a hot summer. As the south is approached the ratio decreases, with the increase of the total temperature till it is inverted, so that in some coastal districts of the extreme south with a low rainfall the best crops are obtained in cool, wet years.

SPRING CEREALS (BARLEY AND OATS). — The values for the provinces of Malmöhus, Kristianstad, Blekinge, South Kalmar and Halland are:—

Temperature	$\left\{ \begin{array}{l} \text{Barley: May} - 0.23, \text{ June} - 0.12 \\ \text{Oats: May} - 0.24, \text{ June} - 0.10, \text{ August} - 0.35 \end{array} \right.$
Precipitation	$\left\{ \begin{array}{l} \text{Barley: May} + 0.22 \\ \text{Oats: May} + 0.29, \text{ June} + 0.32. \end{array} \right.$

In the other provinces of South Sweden, unlike the preceding case, the temperature values for  $r$  are positive during all the months except June and July. In Central Sweden the temperature values for barley and oats are positive in March, April and August, and negative in May, June, and especially in July ( $r = -0.31$ ). Except in August the value of  $r$  for rainfall is always positive:—

Barley:	May + 0.21; June + 0.23; July + 0.28
Oats:	May + 0.32; June + 0.34; July + 0.35.

The best barley and oat crops, therefore, are obtained in wet years. As the north is approached rainfall becomes more and more abundant so that all relation between rainfall and grain yield tends to disappear while the effect of temperature becomes more and more marked, the correlation coefficient becoming positive for every month without exception, the maximum value — *Barley* + 0.38, *Oats* + 0.40 — occurring in June. It may be concluded that the most important meteorological factor for spring cereals is precipitation in Central and South Sweden (especially the May and June rains), and temperature in North Sweden.

FORECASTING THE YIELD. — The use of the correlation coefficient makes it possible to forecast the yield of a future crop within certain limits which are all the more certain as the value of  $r$  is higher. Thus, for example, in the province of Malmöhus, the author was able to determine the following coefficients of regression (1) for winter cereals:—

1) For each degree of the average temperature of August above the normal, the yield in grain *decreases* by 0.18.

2) For each degree of the average temperature of November and December above the normal, the yield *decreases* by 0.50.

3) For each degree of the average temperature of January and February above the normal, the yield *increases* by 0.14. ●

(1) See *R.* March, 1918, note to No. 279, p. 315. (*Ed.*)

4) For each 10 mm. of rainfall above the normal in October and November, the yield *decreases* by 0.06.

In 1916-17 the average temperature of August exceeded the normal by  $0.2^{\circ}$ , that of November and December exceeded it by  $1.6^{\circ}$ , but that of January and February was  $1.7^{\circ}$  below the normal. The rainfall for October and November was 30 mm. above the average. If the figures given above be applied a total decrease in yield is found which may be expressed by 1.3 (coefficient of regression). The author gives several other such examples, all of which show the practical value of the coefficient of correlation in forecasting the harvest.

1328 - **The Effect of Temperature and other Meteorological Factors on the Growth of Sorghum.** — VINALL, H. N. and REED, H. R., in the *Journal of Agricultural Research*, Vol. XIII, No. 2, pp. 133-147 + 2 Plates. Washington, April 8, 1918.

The varieties of sorghum studied were Sumac, Red Amber, Honey, Blackhull Kafir, Dwarf Milo and Feterita, and the meteorological observations were made at Chillicothe (Texas), Chula Vista and Bard (California), and Puyallup (Washington), stations having widely different climatic conditions. The contrast between the last two is very marked, Bard having a high temperature and a high percentage of sunshine during summer, whereas the maximum temperature at Puyallup does not reach the optimum temperature for sorghum ( $33^{\circ}$  C.). These conditions greatly influence the growth of the plant. The data collected from 1915 to 1916 lead to the following conclusions: —

1) *Sorghum is a plant specially adapted to tropical and semi-tropical climates and cannot thrive in cold regions.* — At Chillicothe and Bard, where the average temperature during the vegetative period is  $25.8^{\circ}$  C. and  $28.2^{\circ}$  C. respectively, sorghum does very well and ripens in 106 and 129 days after sowing, reaching an average height of 68 and 82 inches and a stem diameter of 0.79 and 0.68 inches. At Chula Vista, where the average temperature is much lower ( $18.2^{\circ}$  C.), the grain ripens a month late (average date for the six varieties of sorghum; November 14), and the vegetative period lasts 141 days. At Puyallup, with a temperature of  $15.3^{\circ}$  C., sorghum does not ripen, so that it may be considered outside the sorghum belt. The difference between the total positive temperature (i. e. above  $19^{\circ}$  C.) during the vegetative period —  $1052^{\circ}$  C. at Chula Vista and  $897^{\circ}$  C. at Puyallup — is very small, and not sufficient to explain the different behaviour of the plant in the two localities. Another meteorological factor, the amount of sunshine is concerned in this.

2) *Application of LINSSER'S law to sorghum.* — The total positive temperature is  $1052^{\circ}$  C. at Chula Vista,  $2353^{\circ}$  at Bard,  $1682^{\circ}$  at Chillicothe. According to LINSSER the amount of heat required for the development of a certain stage is not the same in all parts of the area of distribution of a plant but increases with the annual total of positive temperatures. By dividing the total positive temperatures for the vegetative period by the annual total the "physiological constant" is obtained. If this law be applied in the present case the physiological constant is about 0.53 (Chillicothe 0.539, Bard 0.530, Chula Vista 0.526).

3) *Effect of sunlight*. — The percentage of sunshine at Puyallup (46.4) is much lower than that of the other stations, especially that at Chula Vista (68.4). Besides lowering the temperature, a low percentage of sunshine helps to lengthen the vegetative period till it may, as at Puyallup, prevent ripening altogether.

4) *Effect of high temperature on flowering and the formation and ripening of seeds*. — High temperatures at the beginning of flowering are detrimental to the plant and decrease the yield considerably. In 1915 the seed was sown in April so that flowering and fruiting occurred in the middle of summer, at high temperatures, and the yield in grain was low. In 1916 sowing was in mid-June and flowering and fruiting at the end of summer and in autumn respectively, when the temperature was much lower, and a good yield was obtained. Sowing should be timed so that flowering and fruiting will take place under favourable climatic conditions.

1329 — *The Influence of Rainfall on the Fruit Crop in Norway*. — SEARD, A. M., in the *Tidsskrift for det Norske Landbruk*, Year XXV, Part. 8, pp. 305-332. Christiania, 1918.

Apples and pears can be successfully grown in the following regions of Norway :— North Bergenhus, Jarlsberg and Larvik, Nedenes, Smaalene, Lister and Mandal, Buskerud, Stavanger, Hedemarken, Akershus, Bratsberg, South Bergenhus, Kristians, Romsdal, South and North Trondhjem.

The average crops from 1907-1916 were sufficient for local needs. But there is the serious disadvantage, that the crop varies greatly year by year, thus largely exposing the market to foreign competition. Thus, taking the average crop as 100 we get :— in the Buskerud, 125 % in 1909 and 41 % in 1916 ; at Lier, 150 % in 1909-11 and only 30 % in 1916 ; in Balestrand, 150 % in 1911 and 70 % in 1916.

Thus there are years in which the supply exceeds the demand and others when the supply is completely insufficient. To avoid these difficulties, the factors of the variations given above must be known and, given that these variations persist while the conditions of soil and crop remain unchanged, it is obvious that the primary cause of the phenomenon must be sought in the weather conditions.

The author gives the results of a series of researches on the relationship between the yield in fruit and the rainfall. The following localities (centres of production) were studied : — Faaberg, Furnes, Edsvold, Vestre Aker, Rygge and Moss, and Norderhov, all situated in south-eastern Norway (Åstlandet).

From the examination of abundant observations it was concluded : — 1) that there is a direct ratio, a positive correlation, between the crop-yield and the rainfall from March to June of the previous year ; 2) that there is an inverse ratio, a negative correlation, between the crop-yield and the rainfall of September-October of the previous year. In spring the plant requires a large amount of plastic material so as to satisfy the needs of intense and quick growth :— leafing, flowering, setting, formation of flower buds for the following year. The absorption of material from the soil is subor-

dicated to the presence of water in sufficient amount to dissolve and carry such material.

Insufficient moisture at this moment is fatal to the plant ; part of the very young fruit becomes detached on account of lack of food material, and the next year's fruit buds develop badly or incompletely, resulting in a poor spring flowering. From this it will be seen that there is a positive correlation between the fruit crop and the total rainfall from March to June.

During the second half of summer and the beginning of autumn, dry, warm weather is required to mature the spring wood, the fruit, the fruit buds, and the store of reserve materials necessary for recommencing growth in the following spring. When this period is damp and rainy growth continues longer, to the detriment of the reserve material. As a result there is a) *incomplete maturity of the buds and wood and also, in consequence, decreased resistance to cold* ; b) *an insufficient store of reserve materials and, in consequence, limited and poor flowering in spring*.

There is, therefore, a negative correlation between the fruit crop and the total rainfall from September to October. Below are given the data for the Faaberg region, the rainfall data being taken from the nearest meteorological station, that at Lillehammer.

*Data showing the existence of a ratio between the fruit crop and the total rainfall for the periods March-June and September-October (average rainfall : March-June 169 mm ; September-October, 125 mm).*

Yield		Rainfall		
Years	in % of the average	Years	March-June	September-October
1909	150 %	1908	138 mm	48 mm
1911	130	1910	260	56
1914	120	1913	142	42
1913	115	1912	178	119
1915	80	1914	175	67
1907	40	1906	157	113
1908	25	1907	238	135
1910	20	1909	171	169
1912	30	1911	145	134
1916	20	1915	71	36

There are similar conditions in other localities. A good crop does not always correspond to abundant spring rain or too little summer-autumn rain. The number of flowers does not mean a corresponding number of fruits ; the action of late frosts at the moment of flowering and mists during setting may ruin the crop, even though flowering has been most abundant. This explains the variations in the above Table. As the north and west are gradually approached, with the increase of the total rainfall during all the

year, the ratio existing between the rain and the fruit crop disappears, whilst the action of other factors and weather conditions is plainly shown.

On account of the preponderating action of the rainfall the author gives the following advice to fruit growers in Östlandet: —

- 1) Choose varieties very resistant to drought.
- 2) Work the soil deeply so that the plant's roots can grow in length, thus utilising the water stored in the deep layers.
- 3) Give the preference, as intercrops, to potatoes, leguminous plants, carrots, etc. These plants have, at any rate in Norway, only a limited growth up to mid-June and thus only remove a limited quantity of water from the soil. During summer, on the contrary, and at the beginning of autumn, the foliage increases rapidly owing to the absorption of large quantities of water, of which the fruit trees are deprived with advantage.

SOIL PHYSICS,  
CHEMISTRY  
AND  
MICROBIOLOGY

The growth of a crop is only possible through the simultaneous operation of a number of soil factors — water, mineral salts, temperature and oxygen. If any one factor is in defect, or in excess as in the case of temperature, growth is regulated by the amount of this factor present, and is not influenced by an increase in any of the other factors. The chief object in soil management is the removal, in advance, of any possible limiting factor.

The aeration of the soil is a factor in growth which has been neglected in the past. It has only indirectly been recognised in the importance attached to a proper soil texture. The subject is not attracting more attention and it is proposed to refer to some of the recent work and to indicate the directions in which further investigation is desirable.

AERATION AND THE AMOUNT OF GROWTH. — Various determinations have been made of the amount of growth in cultures in which the only variable factor is the degree of aeration.

1) *The effect of increased aeration on the root development of barley.* — In water cultures, HALL (1) found that both root development and growth depend on the amount of aeration.

(1) See R., 1914, No. 12; 1915, No. 571; 1917, Nos. 790 and 795. (Ed.)

2) *The effect of soil texture on growth.* — HUNTER (II) found that root development and growth fell off as the soil was more consolidated.

3) *The effect of adding potsherds or sand to the Pusa soil (III).* — The addition of inert aerating agents like sand, potsherds or broken bricks to Pusa soil (a fine calcareous silt which readily loses its texture) increases the growth very markedly. In the case of Java indigo, where both nitrogen and oxygen are required, the increase is as high as 40 %. To follow the subject further, the structure of the soil must be considered in relation to the root development of the plant. The pore spaces of the soil are taken up by air and water, the latter occurring in thin films round the soil particles. The biological activities of the root hairs and of the soil bacteria involve respiration for which a constant supply of oxygen is necessary and which results in a continuous production of carbon dioxide. Efficient soil ventilation is therefore essential for growth. Recent investigations at Rothamsted (IV) on the composition of the soil atmosphere show that the amount of oxygen in the soil falls as the amount of carbon dioxide rises. The water films contain little oxygen but much carbon dioxide, that is, the oxygen is used up as rapidly as it is supplied.

**VENTILATION OF THE SOIL, AND THE SYSTEM OF FLOOD IRRIGATION IN NORTHERN INDIA.** — Flood irrigation on fine alluvial soils interferes with their ventilation by rapidly destroying the texture and by forming a compact surface crust impermeable to air. One limiting factor — water — is removed but another — the need of aeration — is introduced. Thus over-irrigation actually diminishes the yield. This is shown by results obtained at Quetta where 13 maunds of wheat were obtained with one irrigation and only 8 maunds where three irrigations were given. In any flood irrigation system, a practical compromise between the needs of the plant for air and for water must be worked out. This has been accomplished at Quetta (V) by the proper utilisation of the preliminary watering given before sowing. Under this new system, the yields obtained are often higher than those obtained with the 6 or 7 waterings usually applied. The Quetta results have been shown by experiment to apply to the Punjab (VI) and Sind where almost half the irrigation water now used could be saved. The economic significance of these results becomes apparent when it is remembered that the annual revenue derived from irrigation works in India is £ 5 000 000.

**SOIL, AERATION AND QUALITY.** — It is well known that the quality of vegetable products varies with the locality, but the factors on which quality depends are still undetermined. Breed is undoubtedly one of the most important, and no improvement in cultivation can change a short-stapled cotton into a longstapled kind. Various observations suggest that for each variety to attain its highest quality, adequate soil aeration is necessary. A few examples may be given: —

1) *Barley* — The best malting samples are always grown on open well-aerated soils and never on stiff heavy clays.

2) *Tobacco* — All the tracts in India which have achieved a reputation for the production of tobacco of good quality are those in which aeration is above the average.

3) *Cotton* — Mr. CLOUSTON's results on the open laterite soils at Chandkhuri indicate that soil aeration is one of the factors on which the quality of the staple of cotton depends.

Experience in India shows that crops will not mature properly if soil aeration is interfered with during the ripening period. Recent results obtained at Rothamsted (VII) show that, on cropped land, ripening is associated with a great outpouring of carbon dioxide into the soil atmosphere. The cause of this is not known. It has been suggested that it is due to the death and decay of the fine roots after the flowering period, but this will not explain the observed delay in ripening if air is not supplied during the period of maturation. An interesting field of research lies ready to hand.

OTHER ASPECTS OF SOIL AERATION. — If soil aeration is a growth factor, aeration must influence the distribution of plants, as of grain in India (VIII), and be of importance in ecological studies. CANNON in Arizona and FREE (IX) of the Johns Hopkins University have shown that the poor conditions of soil aeration are correlated with the absence of vegetation in the dry lakes of desert basins, and the zonation of vegetation round these basins may be in correlation with the soil aeration requirements of the plants involved.

The importance of soil aeration in Indian forestry (X, XI, XII) has recently been emphasised by a study of the factors influencing the healthy growth of sal (*Shorea robusta*) seedlings. Whereas water cultures have shown that water in itself is quite harmless, yet water which is held in contact with sal forest soil rapidly becomes highly injurious to the roots of the seedlings. Any factor which increases the amount of moisture in the soil, such as shade or bad drainage, accentuates the injurious action. Rain-water held in contact with such soil is found to become heavily charged with carbon dioxide and impoverished as regards its oxygen supply. In water culture experiments, a high carbon dioxide and low oxygen-content have been proved to be injurious to the roots. There are good grounds for believing that, in addition to sal, many of the most important Indian trees are very sensitive to soil-aeration, and a careful study of this factor appears to be of primary importance in Indian forestry not only on account of its effect on the establishment and development of seedlings but also because of its probable influence on the growth of older trees and its possible connection with injurious diseases.

1332 — Copper and Zinc as Antagonistic Agents to the "Alkali" Salts in Soils. —

LIPMAN, C. B. and GERICKE, W. F., in the *American Journal of Botany*, Vol. V, No. 4, pp. 151-170 + 13 Tables + Bibliography of 11 Publications. Lancaster, Pa., April, 1918.

The antagonistic salt effect is now regarded as one of the established facts in plant physiology as in animal physiology. In the large amount of work done on the antagonism between salts, the heavy metals have received very little attention, while the alkali and alkali-earth metals have been tested in many ways. The authors consider the chief work on the heavy

metals (LOEB (1), CLARK, TRUE (2) and GIES, HAWKINS, LILLIE, etc.) and remark on the negative results obtained with copper and the lack of data, as far as regards the more important functions of plants, on the antagonistic action of that metal to the alkalis. As the authors had observed the stimulating effect of copper and zinc in certain cultures, they undertook to study the antagonistic action of copper (and of zinc, whose stimulating effect seems to indicate a similar method of action) to the toxic effects of "alkali" salts as regards the living cells of higher plants (3).

The plants used as indicators were a strain of barley (*Hordeum vulgare*). They were sown in pots and optimum and uniform moisture conditions were maintained in the soils. Some of the common salts of alkali soils, viz. chloride, sulphate and carbonate of sodium, were used as toxic agents, being added on a percentage basis of the dry weight of the soils. The antagonistic agents were the chlorides and sulphates of copper and zinc and copper carbonate, added to the salt-treated soils in quantities varying between certain limits (parts per million of dry soil). Two types of soil were employed, one sand, the other clay. The plants were grown to maturity, harvested, dried at 100° C., and weighed; the roots, stem and grain were weighed separately. The results were assembled in table form for each of the 7 series of cultures (including respectively:  $\text{CuSO}_4$  versus  $\text{Na}_2\text{SO}_4$ ;  $\text{CuCl}_2$  versus  $\text{NaCl}$ ;  $\text{CuCO}_3$  versus  $\text{Na}_2\text{CO}_3$ ;  $\text{ZnSO}_4$  versus  $\text{Na}_2\text{SO}_4$ ;  $\text{ZnCl}_2$  versus  $\text{NaCl}$ ;  $\text{ZnSO}_4$  versus  $\text{NaCl}$ ;  $\text{CuSO}_4$  versus  $\text{Na}_2\text{SO}_4$ ).

The authors state, without qualification, that the data they have thus obtained are the first evidence ever published of the antagonistic action between heavy metals and alkali salts. The antagonistic action is equally if not more marked when 4 ions are introduced into the soil, as in the case of the  $\text{CuSO}_4$  versus  $\text{NaCl}$  culture. Although only one crop was grown in sand, the majority being in clay, similar evidences of marked antagonism were noted.

The authors call attention to the importance of these results from the point of view of their possible practical application, an application that is also economic owing to the small quantities of the metals required to antagonise large quantities of alkali salts and, seeing that zinc is almost as effective as copper in the direction noted, this fact may indicate possibilities in the same line with other and cheaper metals.

1333 - The Effect of Heat on some Nitrogenous Constituents of Soil. — POTTER, R. S. and SNYDER, R. S. (Department of Soil Chemistry, Iowa Agricultural Experiment Station), in *Soil Science*, Vol. V, No. 3, pp. 197-223 + 4 Figs. + Bibliography of 17 Publications. Baltimore, March, 1918.

In investigations on the effect of heat on the nitrogenous constituents of soil only the ammoniacal and nitric nitrogen are usually estimated. The authors estimated the amino-acid nitrogen and soluble non-protein nitrogen as well. Three loam and one peat soils were subjected to the following treat-

(1) See R., Feb. 1915, No. 155. — (2) See R. Oct. 1915, No. 1020 (Ed.).

(3) For the limits of the tolerance of plant life for sodium salts contained in the soil, see R., Feb., 1917, No. 132. (Ed.)

ments : — a) Two hours' dry heat at 100° C., b) two hours' dry heat at 200° C., c) heating in the autoclave for 3 hours ; d) heating in the autoclave for 3 hours on 3 successive days. In each case the soils were inoculated with fresh soil emulsion and left to incubate for 10 and for 20 weeks respectively. A control series was not inoculated.

*Results.* — In all soils subjected to heat the ammonia increased as the temperature was raised ; in the peat soil heated to 200° C. excessive volatilisation of ammonia was observed. The amino-acid nitrogen gave results similar to those of ammonia except in the case of peat soils, which underwent very little change under the different treatments.

Dry heat at 100° C. modified very little the nitric nitrogen content of the soils, whereas heating in the autoclave increased it considerably in every case. Nitric nitrogen disappeared almost completely at 200° C. of dry heat. All treatments caused an increase of soluble non-protein nitrogen ; this increase was less marked in the peat soil.

In the three loam soils incubation for 10 weeks after treatment with dry heat at 200° C. caused an increase in ammonia. In two cases incubation for 20 weeks also caused an increase in ammonia, but to a lesser extent than incubation for 10 weeks ; in one case it decreased the ammonia. Incubation had very little effect on the ammonia content of peat soil subjected to dry heat.

Ten weeks' incubation always caused a decrease of amino-acid nitrogen, but a further ten weeks' incubation increased it. Nitric nitrogen increased during both periods of incubation. The soluble non-protein nitrogen in peat soil always decreased during incubation, but increased in loam soils heated to 200° C.

1334 — **Studies on the Correlation between the Production of Carbon Dioxide and the Accumulation of Ammonia by Soil Organisms.** — NELLER, J. R. (Dept. of Soil Chemistry and Bacteriology, New Jersey Agricultural Experiment Station), in *Soil Science*, Vol. V, No. 3, pp. 225-239 + 5 Figs. + Bibliography of 14 Publications., Baltimore, March, 1918.

As the decomposition of organic matter in soil is generally a biological process, it is measured by various indices of biological activity, the most common of which are plate-counting, ammonification and nitrification. Ammonia determinations being the easiest and supplying much data, the author studied the relation between ammonia accumulation and carbon dioxide production, between which there appears to be an optimum ratio on which the more or less favourable conditions of the soil depend. To this end the author studied the decomposition of organic matter in soils to which had been added both pure and mixed cultures of bacteria or fungi.

During a period of 12 days the production of carbon dioxide was found to be more uniform than the accumulation of ammonia but, as a rule, a greater production of carbon dioxide (with pure cultures) was accompanied by a marked accumulation of ammonia when 1 % of cottonseed meal or alfalfa were added to sandy loam. Pure cultures of fungi (*Aspergillus niger*, *Trichoderma*, etc.) oxidised more carbon, but caused the accumulation of much less ammonia than bacterial cultures. Soil infusions affected ammo-

nia accumulation in a way similar to fungi, but produced more carbon dioxide. Mixtures of pure cultures of bacteria showed no antagonism and in some cases a symbiotic relation appeared to exist.

It seems that when studying the optimum ratio between carbon-dioxide production and ammonia accumulation, other kinds of organic matter and the nature of the soils, as well as the effect of various manures and fertilisers should also be studied. The action of pure cultures of bacteria, actinomycetes, fungi, mixed so as to form a synthetic soil flora, also deserves study so that, in estimating the action of the natural flora of the soil, it may be possible to improve the soil and obtain from it the maximum yield without deterioration to it.

#### MANURES AND MANURING

**1335 - Nitrogen Fixation in Manure.** — I. TOTTINGHAM, W. E., (Wisconsin Agricultural Experiment Station, Madison), The Increase of Nitrogen in Fermenting Manures, in *The Journal of Biological Chemistry*, Vol. XXIV, No. 3, pp. 221-225. Baltimore, 1916. — II. FULMER, H. L. and FRED, E. B., (University of Wisconsin, Madison), Nitrogen-Assimilating Organisms in Manure, in *the Journal of Bacteriology*, Vol. II, No. 4, pp. 423-434. Baltimore, 1917.

I. — Various investigations (lasting from two to several months) on fermenting manure have nearly always shown more or less considerable loss in nitrogen; an increase in nitrogen has but rarely been observed (1). During recent work on the changes in a fermenting mixture of cow and horse manure an increase in nitrogen was observed after two and four weeks. This increase was followed by so large a decrease that after twelve weeks the loss in nitrogen was complete. The increase in the nitrogen content is much greater in straw-littered than in unlittered manure.

This fixation phenomenon was confirmed by laboratory control tests. The manure mixture was kept either in covered galvanised iron pails or inoculated with mannite or other solutions. The results showed manure to contain nitrogen-fixing bacteria of considerable activity, especially when mixed with straw, which appears to be an important source of energy for these microorganisms. It is obvious that the increase of nitrogen in manure at the beginning of fermentation may prove of practical value in manuring soil if this increase is not counter-balanced by a simultaneous loss in organic matter. Experiments with straw-littered manure (gathered fresh and placed in covered boxes out of doors during the winter months so as to limit fermentation) applied to a rotation of maize, barley and clover, showed such manure to increase the yield in maize grain by 5.3 % and the yield in maize stover by 7.4 %, as compared with fresh manure with straw. This difference disappeared with barley and was reversed with clover. The results of these experiments, which lasted six years, were in favour of limited fixation of manure if the nitrogen so fixed can be utilised at the time of application.

II. — Later experiments made with liquid and solid cultures showed nitrogen fixation in fermenting manure to be due to certain forms of bacteria which appear to belong to different groups. The chief agent of nitrogen

(1) See R. Sept. 1917, No. 797. (Ed.)

fixation in manure, however, seems to be *Bacterium azophile* n. sp., present in large numbers in fermenting manure. The increase in nitrogen when this bacterium is grown on manure extract is from 3 to 5 mg. per 100 cc. of solution. The optimum temperature for the development of nitrogen fixing bacteria in manure appears to be 28°C. *Bact. azophile* seems to be widely distributed in nature.

- 1336 - **The Possibility of Obtaining Nitrogenous Fertilizers by Utilising Waste Materials for the Fixation of Nitrogen by Nitrogen-Fixing Bacteria.** — DORVLAND, C. I. T. (Scientific Proceedings of the Society of American Bacteriologists), in *Abstracts of Bacteriology*, Vol. II, No. 1, p. 2. Baltimore, 1918.

While studying the energy relations of a soil flora experiments were made to determine which waste materials might serve as sources of energy for nitrogen-fixing bacteria. It was found that nitrogen fixation took place when either molasses, orange juice, lemon juice, grape fruit juice, wheat, oat, barley, rye or flax straw were used as sources of energy. Waste paper, wood wastes, grass residues and beet and cane sugar residues will probable serve in the same way. Under natural conditions nitrogen may be fixed by bacteria much more economically than by our present laboratory methods. The writer suggests that it is probable that the fixation of nitrogen by bacteria may be accomplished as cheaply as by electricity or even by a catalytic chemical process such as BUTCHER'S cyanide process. The production of cheap nitrogen by the bacterial process will be attained by utilising waste materials as sources of energy, together with the correct combination of symbiotic microorganisms and the development by selection of highly efficient nitrogen fixing strains. These must be combined with a simple mechanical manipulation, with final evaporation by solar heat. A modification of the rapid vinegar process for waste liquids and a modification of the activated sludge process for solid materials such as pulps, straws and waste paper are possible points of departure for mechanical manipulation.

- 1337 - **Studies on the Absorption of Ammonia by Superphosphate: "Ammonium Superphosphate"** (1). — BRIOTUX, C., in the *Comptes rendus des Séances de l'Académie d'Agriculture de France*, Vol. IV, No. 21, pp. 632-638. Paris, June 12, 1918.

Since the war, the consumption of pyrites and sulphuric acid has had to be limited everywhere in Europe, especially for the manufacture of manures. As this has been particularly the case in Germany, in that country the sulphuric acid required to absorb the ammonia to produce the sulphate has been suppressed, and the ammonia (obtained from sewage-water, gas water or cyanamide) is absorbed by calcium superphosphate made with sodium bisulphate, a bulky and worthless residue of powder works. In this way a new phosphatic and nitrogenous manure has been obtained which is called, in the lack of another name, "ammonium superphosphate" and which will act on the plant contemporaneously with all its nitrogen and all its phosphoric acid, in spite of the reverted state of the latter.

As this new manure is of interest under present conditions, the author

(1) See R., March 1916, No. 272. (Ed.)

has prepared a small amount to study its chemical properties, his observations being summed up in the present paper.

When insoluble tricalcic phosphate is attacked by sulphuric acid we get calcium sulphate and calcium acid-phosphate which corresponds to one molecule of phosphoric acid for one molecule of lime instead of three. If the superphosphate is treated with ammonia gas, the latter does not saturate, as one might expect, the acidity of the phosphate; it acts on the calcium sulphate, forms ammonium sulphate and reconstitutes the tricalcic phosphate, the reaction being as follows:—

It would thus seem that there is a grave disadvantage; water-soluble phosphate had been formed and then rendered insoluble again. But the author points out that the cohesion of this tricalcic phosphate is not the same; it has become such that it dissolves almost integrally (after preparation) in ammonium citrate and 2 % citric acid. The superphosphate used for the tests had the following chemical composition:—total  $\text{P}_2\text{O}_5$ , 15.60 %;  $\text{P}_2\text{O}_5$  soluble in ammonium citrate, 14.56 %; water-soluble  $\text{P}_2\text{O}_5$ , 13.03 %. After saturating with ammonia gas and leaving in a thin layer to air dry for some hours, the composition was:—total  $\text{P}_2\text{O}_5$ , 15.80 % (1);  $\text{P}_2\text{O}_5$  soluble in ammonium citrate, 13.10 %; water-soluble  $\text{P}_2\text{O}_5$ , 1.53 %;  $\text{P}_2\text{O}_5$  soluble in 2 % citric acid, 14.10 %; ammoniacal nitrogen, 4.97 %.

As regards the solubility of its phosphoric acid in the usual reagents, "ammonium superphosphate" can, therefore, be considered as superior to basic slag.

It is true that the cohesion of the tricalcium phosphate obtained increases little by little with time and that the citrate solubility diminishes, but the new product remains soluble in 2 % citric acid.

The author has made no cultural tests, but he points out that such tests gave good results in Germany. Besides, the solubility of "ammonium superphosphate" in weak reagents shows that it should be easily dissolved by the agents in the soil.

1338 — Production of Calcium Phosphate at Curaçoa. — *Handelsberichten*, Year XII, No. 595, p. 286; No. 591, p. 231. The Hague, 1918.

The calcium phosphate found at Curaçoa and in the two neighbouring islands, Aruba and Bonaire, is mostly derived from guano and marine animals.

These phosphates have been long worked, with great fluctuations and even stoppages. In the island of Aruba the working was begun in 1881 and attained its maximum in 1907 when 35 000 metric tons were exported. In the island of Curaçoa the highest exportation (32 000 metric tons) was made in 1884.

(1) Content slightly higher than that of the primary superphosphate on account of the loss of the water of crystallisation of the calcium sulphate; for 17 gm. of ammonia fixed, 18 gm. of water are displaced. (*Author*.)

[1327-1338]

Owing to the exceptional conditions created by the war, the exportation has decreased enormously, as is plainly shown by the following figures, giving exportation from the "Colonie de Curaçoa": — in 1913, 34 772; in 1914, 21 720; in 1915, 31 308; in 1916, 14 468; and in 1917, 4 000 metric tons.

1339 — On the Diffusion of Aluminium-Ions in the Plant World. — STOKLASA, J. with the collaboration of SEBOR, J., ZDOBNICKY, W., TYMICH, F., HORÁK, O., NEMEC, A., and CWAC, J., in the *Biochemische Zeitschrift*, Vol. 88, Pt. 4, pp. 292-322 + 10 Tables + Bibliography of 17 Publications. Berlin, 1918.

AGRICULTURAL  
BOTANY,  
CHEMISTRY  
AND  
PHYSIOLOGY  
OF PLANTS

The author had long studied the diffusion of aluminium in the plant world (1) and its physiological function. In the present paper he gives the results of the latest researches he has carried out with his collaborators, results that shed new light on the function of aluminium in the various ecological categories of the plant world, that is, 1) xerophytes; 2) hydrophytes and hygrophilous plants; and 3) mesophilous flora.

Before giving his results, the author rapidly considers the literature on the subject, showing the great divergence existing between the opinions regarding both the diffusion and function of aluminium in the plant world, which renders these researches very timely.

The author has obtained most abundant and varied material from nearly every European country. Before analysis the plants were carefully washed, especially the roots, and air dried. The data obtained for each species are given in numerous tables giving the percentage of ash in the dry matter, the percentages of iron oxide and aluminium oxide respectively in the ash and in the dry matter. The material was naturally grouped according to its ecological nature and the general results obtained for each of the 3 groups thus established may be summarised as follows: —

I. — XEROPHYTES. — The xerophilous flora is distinguished by the low content of all the organs of the plant in aluminium-ions. Occasionally barely traces of aluminium-ions can be found, e. g., in the flowers and seeds of Phanerogams, which, at the most, show traces of aluminium oxide. The absorption of very small quantities of the aluminium-ions of the soil constitutes a physiological property characteristic of the xerophilous flora.

I. — HYDROPHYTES AND HYGROPHILOUS FLORA. — The inverse holds good for hydrophytes and hygrophilous plants, which are characterised by a high aluminium content, especially the algae, as is shown by the following amounts of  $Al_2O_3$  contained in the dry matter: — in the Chlorophyceae, *Bryopsis* n. sp., 1.414 % and *Halimeda opuntia*, 1.419 %; in the Phaeophyceae, *Sargassum bacciferum*, 1.512 %; in the Rhodophyceae, *Delesseria*, 2.332 %. In the higher plants the root contains much more aluminium oxide than the epigeal part; thus, in the Equisetaceae, the dry matter of the root may contain from 1.737 to 1.775 % of aluminium oxide, and that of the epigeal part, 0.345 to 0.478 %. The same difference, often still more accentuated, occurs in the Lycopodiaceae, Cyperaceae, Polygonaceae, etc., all

(1) See R., January, 1914, No. 21. (Ed.)

very rich in aluminium. Many hydrophytes and hygrophilous plants contain in the dry matter of their root system from 0.104 to 0.766 % of aluminium oxide and in that of their epigeal part from 0.018 to 0.276 %. The flowers and seeds of the phanerogams analysed always contained aluminium, however, sometimes even in notable quantity. The general biological economy of the organism of hydrophytes and hygrophilous plants shows that the absorption by the cell of the aluminium-ions of the water or soil constitutes a special physiological requirement for these plants. The physiology of the cell here includes a special selective faculty, quantitatively determined for the aluminium-ion, which is concentrated in the higher plants in the roots, rhizomes, tubers or bulbs. In these higher plants, it is the general rule that the epigeal part always contains less aluminium-ions than the subterranean part. The absorption of considerable quantities of aluminium-ions and their deposit amongst the reserve material in seeds forms a characteristic physiological property of the aquatic and hydrophilous flora.

III. — MESOPHILOUS FLORA. — Plants growing in an environment of average humidity and which can be modified within certain limits, belong to the "mesophilous flora" (e.g. certain Graminaceae, Papilionaceae, Caryophyllaceae, etc.). When these plants grow in a rather dry environment the root and epigeal systems are extremely poor in aluminium ions; on the contrary, the same plants, growing in a damp or marshy soil accumulate, especially in their roots, notable quantities of aluminium ions.

There thus seems to be a well defined relationship between the diffusion of the aluminium ions in the plant world and the edaphic and ecological factors.

1340 — Experiments on the Resistance of Plants to Cold. — PANTANELLI, E., in *Atti della Reale Accademia dei Lincei*, Series V, Vol. XXVII, Pt. 3, pp. 126-130; Pt. 4, pp. 148-153. Rome, 1918.

Experiments were made with cultures in pots, each of which contained several plants. The pots formed a series of ten, receiving food salts in the following order, making it possible to distinguish the ions most important for the metabolism of the plant: —

- Pot 1) Control, spring water containing chiefly bicarbonate of lime.
- Pot 2)  $\text{NaNO}_3$  (nitric nitrogen; cation with little or no food value).
- Pot 3)  $(\text{NH}_4)_2\text{CO}_3$  (ammoniacal nitrogen; anion negligible).
- Pot 4)  $\text{KHCO}_3$  (potassium; anion negligible).
- Pot 5)  $\text{KNO}_3$  (potassium and nitric nitrogen).
- Pot 6)  $\text{KH}_2\text{PO}_4$  (potassium and phosphoric acid).
- Pot 7)  $\text{MgSO}_4$  (magnesium and sulphuric acid).
- Pot 8)  $\text{Na}_2\text{SO}_4$  (sulphuric acid; cation with little or no food value).
- Pot 9)  $\text{NaNO}_3 + \text{KH}_2\text{PO}_4$  (complete fertiliser; nitric acid, potassium and phosphoric acid).
- Pot 10)  $\text{NaNO}_3 + \text{KH}_2\text{PO}_4 + \text{MgSO}_4$  (complete formula; potassium, magnesium and sodium).

I. — EXPERIMENTS MADE AT TEMPERATURES BELOW FREEZING POINT. — The plants (wheat, beet and sunflower) were grown in cold greenhouses from

January to April and then exposed to temperatures low enough to cause freezing. Wheat and beet, taken from an external temperature of  $11^{\circ}\text{C}$ ., were cooled to  $-4.5^{\circ}\text{C}$ . in 5 hours. The temperature was then raised to  $6^{\circ}\text{C}$ . in 14 hours and, finally, the plants were warmed to room temperature. The sunflower plants, taken from a temperature of  $12^{\circ}\text{C}$ ., were cooled in 3 hours to  $-3.5^{\circ}\text{C}$ ., and kept at that temperature for 2 hours. The temperature was then raised to  $6^{\circ}\text{C}$ . in 15 hours and the plants finally brought to  $12^{\circ}\text{C}$ .

II. — EXPERIMENTS MADE AT TEMPERATURES ABOVE FREEZING POINT.

— The plants (tomato and maize), grown in a cold greenhouse from April to July heated daily to as much as  $38^{\circ}\text{C}$ ., were then exposed to temperatures a little above  $0^{\circ}\text{C}$ . so as to avoid freezing.

CONCLUSIONS. — 1) No immediate relation was observed between resistance to cold and the food value of the salts supplied to the plants. Nitrates diminished the resistance to cold most. Potassium and phosphoric acid inhibited the unfavourable action of the nitrates, but did not increase the resistance of the plants.

2) No relation between growth and resistance to cold was found.

3) No relation was found between the molecular concentration of the cell sap (determined by the cryoscopic method) and resistance to cold. The maize plants which resisted best were those which increased or maintained high osmotic pressure of the cell sap during cooling.

4) There is no relation between resistance or the density of the cell sap in wheat and beet. The most resistant sunflower, tomato, and maize plants were those the cell sap of which was richest in extract.

5) The proportion of mineral principles dissolved in the cell sap does not influence the resistance but, in the case of the tomato, the cell sap of the most resistant plants was poorer in minerals. During cooling the mineral principles of the most sensitive maize plants dissolved.

6) There was no relation between resistance and the proportion of free or combined acids present in the cell sap before cooling, during which the acidity of maize and tomato increased.

7) Before cooling no relation could be found between the resistance and the sugar or plastic carbohydrate contents. Nevertheless, the plants which suffered most were those which, during cooling, disposed of the least sugar, either because much of it had been destroyed or because sufficient starch was not dissolved.

Resistance to cold has, therefore, no connection with the concentration of the cell sap, nor with its content in acids or salts, but with the amount of sugar retained by the cell during cooling. The author intends to study whether the sugar acts only as a source of energy or if it protects the protoplasm against autolysis, as appears to be the case by its strong anti-proteolytic action.

8) These relations were observed in cases of death by freezing as well as in those of death by cooling only. In both cases the drying up of the organs was proportionate to the deterioration suffered, and always occurred although the environment was saturated with moisture.

**1341 - The Influence of the Physiological Condition of the Seed upon the Course of Subsequent Growth and upon the Yield; the Effects of Soaking Seeds in Water (1).**

— KIDD, F., and WEST, C., in *The Annals of Applied Biology*, Vol. V, No. 1, pp. 1-12 + 10 Tables + 5 Figs. Cambridge, July, 1918.

Of late years in most researches dealing with the Seed the attention has been almost entirely concentrated upon the question of germination, while little attention has been paid to the eventual influence of treating the grain, which would show how far the physiological condition of the plant in the seed-stage may exert a pre-determining influence upon the whole subsequent course of growth and development. This importance of this question is obvious when it is said that the yield from an equal number of plants of a pure line may vary 50 % or even more, owing to the pre-determining influence of the physiological condition of the seed as affected by environmental conditions both before and during germination.

The authors undertook to study this predetermining influence and, in the present paper, give the first results obtained by immersing the seeds in water at 17°C. for 8, 24, 48 and 72 hours. The seeds used were those of the pea (*Pisum sativum*), dwarf bean (*Phaseolus vulgaris*), barley (*Hordeum*), sunflower (*Helianthus annuus*), white mustard (*Brassica alba*), broad bean (*Vicia Faba*), white lupin, wheat and oats. The effects observed on the rate of germination of the various samples thus treated, as well as on the yield of the plants obtained (length of stem and root), lead to the conclusion that *soaking the seed in water may have a marked effect on the subsequent growth of the plant*. The nature of the effect is strongly *specific*, quite different results being obtained by similar treatment upon closely allied plants, as is shown very strikingly by beans. The results of soaking the seeds of the dwarf bean even for 6 hours becomes evident after a month's growth by a decrease of 26 % (as compared with control plants set dry) in the dry weight yield of the tops of the plants. Seeds of the same species, soaked in water for 24 hours before sowing, showed the most rapid and vigorous germination, while later, 12 days after sowing, the total length of these plants as compared with the controls set dry was as 2.4 : 13.8.

The results obtained with the Broad Bean are quite different: the effect of soaking the seeds was found to be increasingly beneficial, not only on the percentage of germination, but also upon the size of plant produced. Thus, 3 weeks after sowing, the average height of the plants produced from seeds planted dry was only 4 cm. as compared with 10.4 cm. in the case of those soaked for 3 days before sowing.

The photographs accompanying the article show clearly the effect of soaking the seed on the growth of the plants.

**1342 - The Influence of Temperature on the Germination of the Seeds of the White Mulberry.** — ACQUA, C., in *Informazioni seriche*, Year V, No. 8, pp. 131-132. Rome, April 20, 1918.

Laboratory germination tests of white mulberry seeds, distributed gratis by the Italian Ministry of Agriculture, for forming "prati di gelso"

(1) See also R., June, Aug. and Sept. 1917, Nos. 533, 717 and 804. (Ed.)

(dwarf-plant plantations). In practice, a germination percentage of 50 % is satisfactory.

The tests show that, at 20°C., germination commences on the 5th day, taking place gradually, so much so that a final total of 23 % is obtained. At 25°C., germination begins on the 4th day, and the total is 34 %. The optimum is obtained at 30°C., with vigorous germination on the third day and a total of 62 %. At 35°C., there is diminished intensity (a total of 50 %) and, at 40°C., germination ceases. The influence of the temperature is, therefore, important, and growers should take it into account.

The experiments all show that the seeds are not harmed when they remain at a low temperature in a damp room or in the soil, as happens, for example, with autumn sowing. Growers should not be alarmed, therefore, if the season is cold and the young plants do not appear; cultivation should, on the contrary, be continued. But it may be more advisable to delay sowing until the temperature is sufficiently high to assure more rapid germination. It is not necessary to wait for the optimum temperature and a lower temperature may even be considered as sufficient, provided it is not too low.

As regards the amount of heat necessary for completing germination, the author shows that the nearer the favourable conditions of temperature are approached that amount is smaller.

It still remains to be seen whether the young plants obtained by using various quantities of heat have the same strength and subsequently develop equally quickly. The author is continuing his researches on this subject.

1343 - Mutation Observed in a Pure Strain of Two-Rowed Barley (*Hordeum distichum* L.), in Bavaria. — KIESSLING, L., in *Zeitschrift für induktive Abstammungs- und Vererbungslehre*, Vol. XIX, Pt. 3, pp. 145-159. Leipzig, June, 1918.

PLANT  
BREEDING

In 1912 the author described a new variety of two-rowed barley obtained by mutation in the Vriesian sense in the 9th generation of a pure strain of *Hordeum distichum* described by the symbol Fg2. The new variety, described by the symbol Fg3, has the following characters:—

- 1) Leaves pale green as a result of decrease in the amount of chlorophyll and the number of chromatophore cells and chloroplasts.
- 2) More abundant tillering and greater development of foliage.
- 3) Longer ears and awns, shorter, but more numerous internodes, lighter straw.
- 4) Higher yield in grain.
- 5) High water content of the vegetative parts, lower resistance to cold, greater susceptibility to the action of external agents.

Numerous methodical observations and investigations made since 1912 show this variety to have remained absolutely constant so far, transmitting its characters integrally from generation to generation. It is, therefore, for unknown reasons, a true mutation, i. e. an unexpected hereditary variation. To what category of mutations does it belong? Is it a case of *progressive mutation* due to the appearance of new factors (determinants) capable of influencing the manner of growth and the formation of tissues, or a *mutation by loss* due to the disappearance of one or more factors?

The most striking character of the mutation is lack of chlorophyll with which, as easily explained physiological correlations, might be connected the other differential characters, or at least, many of them. The appearance of the new variety could then be explained by the loss of one or more of the factors governing the formation of chlorophyll. To prove whether this be really so the author made hybridisation experiments from 1911 onwards.

The mutated plant Fg3 was twice crossed with the parent Fg2, first, in 1911, in the sense Fg3 ♀ × Fg2 ♂, then, in 1912, in the sense Fg2 ♀ × Fg3 ♂. The hybrids of the  $F_1$  of both of these crosses were of a distinctly darker green than the form Fg3 and it was not possible to distinguish them with certainty from the Fg2 form. In the  $F_2$  generation the averages from ten determinations were: — 2370 pale green plants, 9073 green (intermediate colour) plants, and 2591 dark green plants. The figures correspond to the Mendelian ratio 0.7:2.6:0.7. The theoretical ratio would be 1:2:1 (the excess of plants of intermediate colour being attributable to the fact that all doubtful cases were usually placed in this category). This ratio is that of a monohybrid.

If the designation  $G^x$  is given to the chlorophyll factors common to the two forms Fg2 and Fg3 and the designation  $G^v$  to the factor which has disappeared in the Fg3, the following gametic formulae are obtained:—

$$Fg2 = G^x G^x G^v G^v \quad Fg3 = G^x G^x g^v g^v$$

$F_1 = G^x G^x g^v g^v$  (darker than Fg3 and probably lighter than Fg2).

$$F_2 = 1 \underset{\text{as dark as Fg2}}{G^x G^x G^v G^v} + 2 \underset{\text{intermediate}}{G^x G^x G^v g^v} + 1 \underset{\text{as light as Fg3}}{G^x G^x g^v g^v}$$

This would confirm the hypothesis of mutation by loss though it would be impossible to say whether  $G^v$  had really *disappeared* or was merely *latent*. In none of the numerous hybridisation tests did this factor reappear even sporadically. It therefore seems probable that the homozygous plant, Fg3, lost not only one factor, but a pair of factors.

As has already been said, the Fg3 form is distinguished not only by the colour of its leaves, but also by other characters, the existence of which may be considered to be an effect of loss of chlorophyll. Thus, the foliage tends to develop more to make up for the loss of assimilating power of the green surface, the total water content increases, the number of stomata decreases, etc. Nevertheless all these adaptations do not entirely compensate for the deficiency of chlorophyll, and the yield in grain of Fg3 remains inferior to that of Fg2. Moreover, the low resistance to cold of Fg3 is clearly connected with the higher water content of its tissues.

1344 - The Relation between Colour and other Characters in Certain Avena Crosses. — LOVE, H. H. and CRAIG, W. T., in *The American Naturalist*, Vol. LII, Nos. 620-621, pp. 369-383. New York, August-September, 1918.

The paper under review gives the results of a series of crosses between *Avena fatua* and *A. sativa* made in order to study the inheritance of awn development, glume colour and pubescence.

CHARACTERS OF THE PARENTS. — *Avena fatua*: — glumes brown or

black, many awns, pubescent both inside and outside. *Avena sativa*: — pale yellow glumes, glabrous and few or no awns.

$F_1$ . — Characters intermediate between those of the parents, brown glumes, inner kernel always without awns, but with sparse dorsal hairs.

GLUME COLOUR IN  $F_2$  AND  $F_3$ . — In  $F_2$  there were three colour types, 310 black, 92 grey, and 18 yellow. Assuming *Avena fatua* to possess the factor determining black **B**, that of grey **G**, and that of yellow **Y**, i. e. the formula **BBGGYY**, and *Avena sativa* only the determinant **Y** and the formula **bbggYY**, the ratio in  $F_2$  should be 12 black-glumed plants: 3 grey glumed plants: 1 yellow-glumed plant. The numbers found (310:92:18) correspond fairly well to those calculated by this ratio (315.00:78.75:26.25), especially as the differences between the first and second are due to the difficulty of distinguishing clearly the plants with pale yellow glumes from those with pale grey glumes. If all the plants with glumes other than black are placed in one group, the ratio obtained is 310 with black glumes: 111 with grey or yellow glumes, corresponding to 3:1. This is confirmed by  $F_3$  which contains 230 black-glumed plants, 57 grey-glumed and 21 yellow-glumed ones.

RELATION BETWEEN COLOUR OF GLUMES AND DEVELOPMENT OF AWNS IN  $F_2$  AND  $F_3$ : — The percentage of awns was obtained by counting the total number of spikelets and the total number of awned spikelets and expressing the second as a percentage of the first. The following table shows these percentages in the black, grey and yellow  $F_2$  plants of the cross *Avena fatua* × *Avena sativa* var. Sixty Day.

		Percentage of awns											Total	
Colour of glumes		0	1-9	10-19	20-29	30-39	40-49	50-59	60-69	70-79	80-89	90-99	100	
	Black	46	25	20	23	12	17	21	23	14	8	2	99	310
	Grey	11	9	6	10	3	10	6	5	1	3	—	28	92
	Yellow	9	7	1	1	—	—	—	—	—	—	—	—	18
	Totals	66	41	27	34	15	27	27	28	15	11	2	127	420

The black oats passed through all the different degrees from fully awned to awnless. The same may be said of the grey oats, except that the total number of awned plants is much lower. On the contrary, the yellow oats differed widely from the two preceding groups by the rareness of their awns the percentage of which did not exceed 30. It seems probable that the yellow factor has an inhibitory influence on the determination of awns. This hypothesis is confirmed by  $F_3$ .

RELATION BETWEEN COLOUR AND PUBESCENCE OF THE GLUMES IN  $F_2$  AND  $F_3$ : — The  $F_2$  of the cross *Avena fatua* × *Avena sativa* var. Sixty Day contained: —

a) 310 black plants, all pubescent, 112 on both glumes of the spikelet, 198 on one glume only.

b) 92 grey plants, 26 of which had pubescence on both glumes of the spikelet, 42 on one glume only, and 24 of which were completely smooth.

c) 18 yellow plants, all of which were perfectly smooth.

These facts show:—1) an incompatibility between yellow glumes and pubescence; 2) the probable existence of two factors for pubescence one of which is linked with the black colour factor. If this be so black oats would have two factors for pubescence, grey oats only one.

Assuming *Avena fatua* to have the formula **BB GG YY PP**, where **B** represents both the black colour factor and one of the two pubescence factors, the second one being expressed by **P**, the formula of *Avena sativa* var. Sixty Day would be **bb gg YY pp**, and its  $F_1$  hybrids with *A. fatua* **Bb Gg YY Pp**. These hybrids form 8 different gametes, the reciprocal combinations of which, taking the inhibitory action of **Y** into account, should give in  $F_2$  48 black pubescent plants, 9 grey pubescent plants and 4 smooth yellow plants. Between plants with pubescent and those with non-pubescent glumes there should be the ratio 57 : 7 (1), and of the 420  $F_2$  plants 374.06 should be pubescent and 45.94 smooth. The numbers found, 378 and 42, correspond very well with these theoretical numbers. The existence of two factors for pubescence, one of which is linked with the factor for black colour, is confirmed by an examination of  $F_3$ .

A series of crosses between *Avena fatua* and *Avena sativa* var. Tartar King gave in the  $F_2$  pubescent and smooth plants in the ratio 15 : 1 or 3 : 1. In the second case ANOTHER TYPE of *Avena fatua* wanting in the determinant **P** and having, consequently, the formula **BB YY GG pp** must be concerned. If this type is crossed with Sixty Day all the yellow and grey  $F_2$  hybrids are completely smooth. This second type of *Avena fatua* then has only one pubescence determinant, that linked with the black colour factor.

1345 — **Methods for Selecting and Improving the Cotton Plant, in Egypt**, — See No. 1356 of this Review.

1346 — **Apple Selection in Canada**. — MACOUN, W. T. (Dominion Horticulturist), in the *Federal Ministry of Agriculture, Canada, Dominion Experimental Farms, Horticultural Branch, Bulletin* No. 86, 154 pp. + 25 Figs. Ottawa, 1908.

As the demand for Canadian apples is continually increasing the Farms and Experimental Stations of that country have been working for some years with the object of obtaining good varieties that would do well in the climate of the North-West by working on 4 lines:—1) selection of seed; 2) acclimatisation and seed selection; 3) selection of bud variations; 4) crossing with wild or half-wild strains with a short vegetative period and very resistant to low temperatures.

1) SEED SELECTION. — By choosing from each tree fruit of good taste, size and colour and sowing their seeds separately, plants may be obtained that tend to retain and transmit the characters for which they were select-

(1) Not taking into consideration the inhibitory action of **Y** this ratio would be 15 : 1.

ed. In 1898 the Ottawa central Experimental Farm had an orchard containing about 500 varieties of apples which could produce countless combinations of characters owing to natural cross-pollination. The seeds of some apples of specially good taste and quality, especially the varieties Mac-Intosh, St. Laurent, Fameuse, Wealthy, Shiawassee, Swayzie, Winter Scott, Salome, Lawyer, Gano, Northern Spy, winter St Laurent, Bullock (American Golden Reinette) were gathered and sown separately. In this way over a thousand varieties were obtained, of which 378 are now showing good promise, particularly Brock, Joyce, Melba, Pedro (from the Mac Intosh variety); Diana, Gerald (from Langford Beauty); Donald, Elmer, Lipton, Niobe, Rocket, Thurso (from Northern Spy); Galetta (from Wealthy); Ramona (from Shiawassee Beauty).

2) ACCLIMATISATION AND SEED SELECTION. — In 1890, an orchard was started with 3000 plants obtained from seeds of apples grown to the north of Riga, Russia. The number of varieties thus obtained gradually diminished, finally forming a small group with notable resistance to cold, which gives to varieties of Russian origin at the north of the 45th parallel marked superiority over those coming from the United States, which, however, are better to the south of that latitude. The varieties worthy of note are Duchess of Oldenbourg, Transparent Yellow, Claire, Neville, Oscar, Percival, Roslin, Rupert.

3) SELECTION OF BUD VARIATIONS. — Some varieties are created by bud variations. Thus, on the Fameuse apple, one or more branches occur bearing apples that are redder than those on the other branches. The Banks red Gravensteins, originating from New Caledonia, are also due to a bud variation. Up to the present, however, but few variations of this kind have been registered.

4) CROSSING. — Several Canadian varieties of apple have been obtained by crossing. For some years this has been carried out at the Agricultural College and Horticultural Station of the province of Ontario, and it is quite probable that good varieties will be produced by this method.

In 1887, the year when the Experimental Farms were opened, that of Ottawa imported from the Botanical Garden of Petrograd (Russia) some seeds of *Pyrus baccata*, a wild apple very common on the banks of Lake Baikal and in other regions of Northern Siberia; this apple is very resistant to strong winds and produces fruits as large as a cherry, astringent, acid and sometimes bitter. These seeds were sown at the Ottawa central Experiment Farm and produced a large number of plants which were distributed to the Experimental Stations of Brandon (Manitoba) and Indian Head (Saskatchewan). In the 20 years during which this Siberian apple has been on trial it has never been damaged by cold. It is somewhat dwarf, with low branches and a strong trunk; the fruit are firmly attached, which explains its resistance to the high winds that are frequent on the prairies of North-West Canada.

In order to enlarge and improve the fruits of *Pyrus baccata*, Dr. W. SAUNDERS carried out, in 1894, a series of crosses between that species and the best Canadian apples, in order to unite in one and the same plant the cha-

racters of "good quality fruit" and "resistance to bad weather." Some of these hybrids are as hardy as *P. baccata*, while producing much larger fruit than those of that species. Cultural tests carried out in a number of localities of the North-West gave really encouraging results.

Similar results were obtained by crossing the best varieties of Canadian and Russian apples with *Pyrus prunifolia*, a wild apple very resistant to cold and producing fruit twice as large as those of *Pyrus baccata* (some botanists consider it as a distinct species, others as the hybrid *Pyrus Malus* × *P. baccata*).

In hybridisation tests with the two above mentioned species pollen of the following varieties was used: — Tetofsky, Duchesse, Wealthy, Anis, Beautiful Arcade, Broad Green, Excelsior, Fameuse, Golden Reinette, Haas, Herren, Krimskoe, Red Mac Intosh, White Mac Mahon, Osimoe, Pewaukee, Red Astrakan, Ribston Pippin, Winter Scott, Simbirsk No. 9, Swayzie, Grey Apple, Talman Sweet, Winter St. Laurent, Transparent Yellow.

After their multiplication and cultivation for some time in the North-West prairie regions, some of Dr. SAUNDERS'S hybrids have proved to be very hardy and they represent a considerable advance in the creation of resistant apples for the North-West.

The following varieties, distinguished by the size of their fruit (diameter from 1.2 to 1.8 in.), are worthy of note: —

Jewel ( <i>P. baccata</i> × Transparent Yellow)	Elsa ( <i>P. baccata</i> × Transparent Yellow).
Columbia ( <i>P. baccata</i> × Broad Green)	Eve ( <i>P. baccata</i> × Simbersk No. 9)
Charles ( <i>P. baccata</i> × Tetofsky)	Dean ( <i>P. baccata</i> × Wealthy).
Silvia ( <i>P. baccata</i> × Transparent Yellow)	Pioneer ( <i>P. Baccata</i> × Tetofsky).
Tony ( <i>P. baccata</i> × Mac Mahon).	

The seed progeny of these hybrids nearly all gave fruit smaller than that of the parents; this fruit was not big enough to stand comparison with those of the less hardy varieties. In order to obtain varieties with large fruit, while still sufficiently hardy to withstand open-air cultivation in the Prairie region, the above hybrids were again crossed in 1904 with the following good varieties of apple (providing the pollen): — Mac Intosh, Baldwin, Cranberry, Duchess, Northern Spy, October, Winter Scott, Simbirsk No. 9, Tetofsky, Transparent Yellow, Ontario, Gideon, Rideau, Haas, August, Walter, Wealthy, Mac Mahon. The seeds from these crosses were sown at Ottawa and gave 407 trees which began to bear fruit in 1910. Most of them produced fruit no bigger than that of the female parent, but 24 produced apples measuring more than 2 in. in diameter, especially the varieties:—

Wapella (Dean × Ontario) with fruit measuring 2.2 × 2.2 in.
Angus (Dean × Ontario) with fruit measuring 2.0 × 2.2 in.
Martin (Pioneer × Northern Spy) with fruit measuring 2.2 × 2.4 in.
Gretna (Pioneer × Northern Spy) with fruit measuring 2.0 × 2.2 in.

As has been seen previously cross pollination occurring naturally between apple trees growing side by side may produce superior strains. There would be a much greater probability of obtaining tangible and sure results were the hybridisation carried out artificially. This the author has already

done by using the varieties : — Anis, Anisim, Antonowka, Baldwin, Baxter, Bethel, Bingo, Cobalt, Crusoe, Duchess of Oldenbourg, Dyer, Danville-Famous, Forest, Glenton, Gravenstin, Hiberna, Lawyer, Lowland, Raspberry, Malinda, Milwaukee, Mac Intosh, Mac Mahon, Newton, Northern Spy, North Western Greening, R. I. Greening, Rosalie, Rouleau, Scott, Stone, Winter Rose; and Walton. At present there are about 1000 hybrids being cultivated, of which 100 have already borne fruit. Some of the best among the new varieties obtained in this way are Vermac (Lawyer ♀ × Mac Intosh ♂) and Rustler (Mac Intosh ♀ × Lawyer Mavis ♂).

1347 — Selection of the Valencia Orange in California, U. S. A. — SHAMEL, A. D., SCOTT, L. B. and POMEROY, C. S., in the *U. S. Department of Agriculture, Bulletin No. 624*, 120 pp. + 4 Tables + 9 Figs. + 14 Plates. Washington, July 25, 1918.

The Valencia orange, widely cultivated in California, has 10 stable characters, as was hitherto believed to be the case, but is composed of a large number of strains capable of being isolated and propagated. These strains differ from each other in the size and shape of the fruit, habit of growth, period of ripening, etc. There are twelve principal strains : —

1) *Valencia strain*. — Trees erect with open heads having large, rounded leaves ; irregular producers. Fruit globular, of medium size, slightly flattened at the blossom end; rind thin, bright orange in colour; juice abundant and sweet; 0 to 10 seeds per fruit with an average of 3. The fully ripened fruit is of good quality, inferior only to the Washington Navel variety.

2) *Corrugated strain*. — Trees with drooping branches and leaves smaller than those of the Valencia variety ; less productive than the Valencia. Fruit oblong or cylindrical; large, thick, very rough, corrugated rind, greenish; little juice of poor quality and flavour; an average of 2 or 3 seeds per fruit.

3) *Long strain*. — Trees similar to Valencia trees in habit of growth and foliage, but less productive. Fruit oval, and much longer than that of the other strains; cross diameter small to medium; rind smooth and of a bright orange colour; juice abundant, sweet and of good quality; an average of 1 or 2 seeds per fruit. The shape of the fruit makes it unsuitable for packing and marketing.

4) *Ribbed strain*. — Branches drooping very irregular production. Fruit globular, sometimes flattened at both ends, small, pale yellow ; rough rind with ribs running from one end to the other, giving the transversal section a polygonal shape; juice abundant but inferior in taste and quality to that of the Valencia strain; an average of 2 seeds per fruit. The shape of the rind detracts from the commercial character of the fruit.

5) *Yellow strain*. — Branches drooping ; annual production more regular than that of the ribbed strain. Fruit globular and small; rind thin, smooth and dark yellow in colour frequently with small red spots or streaks ; an average of 1 seed per fruit. On account of their smallness and colour these oranges are commercially inferior to Valencia ones but ripen about a month earlier, a fact which makes them valuable under certain soil and climatic conditions.

6) *Smooth strain*. — Upright trees producing fruit similar in shape to the Valencia strain, but smaller and much less abundant; the rind is very thin and very smooth (resembling the smooth strain of the Washing On Navel orange), reddish-orange in colour; juice abundant and sweet; an average of 2 or 3 seeds per fruit. Although much less productive than the Valencia orange this strain may prove valuable in California if it is isolated and improved by bud selection.

7) *Barren strain*. — The trees have a drooping habit of growth, are very finely branched and have dense foliage; they grow very vigorously and produce a very large number of flowers but little fruit. The fruit is small with a thick, rough rind and little juice; they are of inferior quality and unsuitable for commerce.

8) *Rough strain*. — Erect trees of vigorous growth tending to produce a large number of suckers and abnormal branches. Fruit inferior in quantity and quality to that of the Valencia strain, with thick, rough rind of an orange-yellow colour, comparatively little juice of medium quality.

9) *Sporting strain*. — The trees vary greatly in production and habit of growth and are extraordinarily vigorous; the leaves also vary greatly in size and shape and the foliage is rather dense. The fruit varies very much and includes all the forms of the Valencia orange as well as others. As a rule these trees produce a few fruits of the Valencia strain which, on the whole, are of little value commercially.

10) *Flat strain*. — Upright trees bearing very little medium-sized fruit flattened at both ends (which gives them a characteristic appearance), with a thick, rough, yellow-orange rind and little juice. They are of no value commercially.

11) *Navel strain*. — The trees resemble Valencia orange-trees in their yield and habits of growth; and their fruit is also similar in shape, size and colour but with a thinner and smoother rind and a small, often rudimentary, navel. This strain, which at times appears as a limb sport on Valencia trees, has been isolated and propagated commercially under the name of "Navelancia". It is of special interest because it is possible, by bud selection, to isolate from it a seedless strain of the Valencia variety.

12) *Willow-leaf strain*. — Drooping branches with leaves resembling those of the willow. Fruit is rarely produced and only in small quantities. It is very small with thick, rough, ridged and yellowish rind and little juice of inferior quality, making it quite useless commercially. It is one of the most interesting bud variations of the Valencia variety.

The eleven last strains are all derived from the Valencia variety (also known as Hart's Tardiff, Hart's Tardy and Hart's late) by bud variations which still occur in large numbers so that it is not unusual to find on one tree, or even on one branch, two or more of these strains. Many of them, as has been seen, are of inferior quality. In choosing bud wood sufficient attention has not been given to the variability of the Valencia variety so that many valueless variations have been widely propagated.

In view of these facts the authors attempted: — 1) to determine the degree of variability of the Valencia orange and the comparative commer-

cial value of the different strains; 2) to determine, by the proportion of inferior oranges in the plantations, to what extent undesirable variations have been propagated; 3) to control, by improved methods of propagation, the entrance of undesirable variations in commercial Valencia orange groves.

During the four years 1912-1915, 105 orange trees of the different strains described above were grown. For each strain annual determinations were made of: —

A) *The number and weight of the fruit of the 1st, 2nd and 3rd grade.* — The 1st, or Orchard, grade includes oranges perfect in shape and colour. The 2nd, or Standard, grade includes fruit which is saleable although faulty in colour, shape, etc. The fruit of these two classes is graded into sizes varying from 288 (the smallest) to 80 (the largest) by a mechanical sizer. The 3rd, or Cull, grade includes unsaleable, inferior quality fruit which are not sized, only their number and weight being recorded.

B) *Average number of seed per fruit*, determined by examining three fruits of each class, i. e., nine in all.

C) *Number of fruits deviating from the standard type.* — For example, in the Valencia strain all ribbed or other forms are considered deviations, and in the ribbed strain all Valencia or corrugated forms, etc. In the Sporting strain fruit of the Valencia type is considered normal.

The results, given in four tables, are as follows: —

**TOTAL FRUIT YIELD.** — On a general average this is between a maximum of 171.6 lb. for a high-yielding Valencia strain and a minimum of 6 lb. for the Barren strain in the following order: — Valencia 131.8 lb., Sporting 127.6 Corrugated 113.5, Long 107.2, Coarse 99.7, Rough 98.5, Low-yielding Valencia 91.1, Small yellow 79.1, Unproductive 77.2, Smooth 75.8, Yellow 72.1, Barren 6.0 lb.

**YIELD OF 1ST GRADE FRUIT.** — High-yielding Valencia 125.9 lb. per tree, Valencia 92.8, Sporting 80.7, Long 66.5, Low-yielding Valencia 61.6, Smooth 60.6, Coarse 53.1, Unproductive 50.0, Yellow 36.5, Small yellow 36.1, Rough 27.6, Corrugated 24.7, Barren 0.9 lb.

**PERCENTAGE OF VARIABLE FRUITS.** — This percentage includes a minimum of 3.4 for the high-yielding Valencia and a maximum of 50.3 for Barren with the following intermediate figures: — Valencia 3.4 %, Smooth 3.4, Low-yielding Valencia 3.8, Long 6.1, Coarse 6.3, Unproductive 7.2, Sporting 12.5, Small yellow 12.9, Yellow 30.6, Corrugated 34.5, Rough 47.3 %.

**CONCLUSIONS.** — The Valencia strain undeniably occupies the first place, it has only a slight tendency to vary (3.4 %) and produced much fruit, mostly 1st grade. It is the best orange from a commercial point of view. If selected the Smooth, Yellow, and Navel strains would prove valuable summer-ripening oranges. The other strains have no commercial value and should be gradually eliminated. By making observations similar to those described during a number of years and recording the results regularly it is possible to estimate definitely the value of an orange and thus to choose for propagation only those distinguished by low variability and a high yield of superior quality fruit. This system, though it does not exclude

completely the possibility of bud variations, makes it possible to obtain a high degree of uniformity and stability in the characters.

AGRICULTURAL  
SEEDS

1348 - Measures taken in Hungary for the Production of Sugar Beet Seed. — *Wochenschrift des Zentralvereines für die Rübenzucker-Industrie Oesterreichs und Ungarns*, Year LVI, No. 14, pp. 122-123. Vienna, April 4, 1918.

By an order dated March 21, 1918, regarding the production of sugar beet seed, the Hungarian Government has made some regulations based on the emergency war laws. The chief articles are given below.

*Article 1.* — Every sugar-beet grower who, in 1918, had undertaken, by a regular contract with a sugar works, to grow 25 hectares or more of sugar beets, is obliged to reserve  $\frac{1}{25}$  of that area for the growth of seedbearing sugar beets.

The *Sugar Beet Seed Commission* (see Art. 10) can allow fractions less than that fixed to be cultivated for seed and may in part or wholly exonerate growers from that obligation beyond a certain limit.

*Art. 2.* — The beet grower must obtain his seed-bearing plants from seed with which he will be specially provided by the sugar works and according to rules laid down by the Ministry of Agriculture.

*Art. 3.* — The beet grower must inform the sugar works as to the quantity of seed-bearers obtained during the first year, and if the works does not make other arrangements, he must keep the seed during the winter. The sugar works will then communicate the information received to the above-mentioned Commission.

*Art. 4.* — On request being made by the growers, the sugar works are required to allow them advances at the time of declaring the seed-bearers up to the value of these and when the beets have been delivered for extracting the sugar.

*Art. 5.* — In the case when the sugar works does not make different arrangements and even if the ordinary cultivation contract has not been renewed, the grower is obliged to replant the seed-bearing sugar beet the following season and give them the usual attention.

*Art. 6.* — If the grower does not replant the seed-bearing beets the sugar works is authorised, after duly informing the Commission, to confide the cultivation of the beets in question to other growers, paying the produce twice the maximum price fixed for ordinary beets if it is in autumn and  $2\frac{1}{2}$  times this price if it is in spring.

*Art. 7.* — The sugar works is obliged to take away from the grower, up till December 1, 1919, the seed he has produced, free at the consigning station, at a price equal to 18 times the maximum price, for that year's beets, that is, at a minimum of 250 kroner per 100 kg (11.37 per lb.) and according to the rules laid down by the Ministry of Agriculture.

*Art. 8.* — The seed-bearing beets obtained in conformity with the present order are considered to be requisitioned, in the sense that they cannot be disposed of in other ways, save by authorisation of the central Commission:

If the sugar works has been unable to obtain the seed it requires in

this way, it can, through the Commission, obtain it from other works having too much seed.

The grower may not retain the seed he requires, but must obtain it from the sugar works.

*Art. 9.* — Each sugar works must inform the central Commission as to the growers undertaking to grow sugar-beet seed, indicating the names, surnames, farms, districts, as well as the area cultivated for seed. This declaration must be made within the 15 days following the publication of the present order or within the 10 days after signing the contract.

*Art. 10.* — To apply this order, a *Sugar Beet Seed Commission* is constituted, including a President, nominated by the Minister of Agriculture, 4 ordinary members and 2 deputies, of which 2 members and 1 deputy must be proposed by agricultural organisations and 2 members and 1 deputy by the sugar works. The secretary of the Commission is the Director of the Plant Breeding Institute or his representative. The expenses of this Commission are paid by the Ministry of Agriculture.

*Art. 11.* — The order does not guarantee the validity of contracts existing between growers and sugar works, contracts which must be in conformity with the dispositions of the said order.

*Art. 12.* — Whosoever directly or indirectly in any way infringes the clauses of the order is liable to a minimum of 6 months in prison and 200 kroner fine. If it be shown that the defendant has even made a profit, he shall pay, over and above the fine, a sum equal to twice such profit. If the goods forming the subject of the infringement are found they will be confiscated:  $\frac{1}{5}$  will be paid to the informer and the remainder, after costs are deducted, will be paid to the Disabled Soldiers Fund.

These measures are to be applied by those responsible for the public peace.

1349 — Tests of Some Spring Wheats (Manitoba, Aurore and Marquis) in Vaucluse, France. — ZACHAREWICZ, in the *Comptes Rendus des Séances de l'Académie d'Agriculture de France*, Vol. IV, No. 29, pp. 825-828. Paris, October 2, 1918.

CEREAL  
AND PULSE  
CROPS

In 1917 and 1918 the author continued his tests at Avignon of Manitoba wheat for autumn and spring sowing, so as to find out whether its resistance to winter cold would be maintained and thus corroborate the results already presented to the Academy of Agriculture at its meeting on July 25, 1917 (1), results that may be thus summed up: Manitoba wheat has shown its hardiness and its resistance to winter cold and may be therefore considered as much as an autumn as a spring wheat for the south of France.

As in the previous year, the trials were carried out in the experiment field of the "Ecole Normale d'Instituteurs d'Avignon", with the collaboration of M. GUÉRIN, Professor of Physical and Natural Science at that school. The seed was drilled on land turned in autumn without any manuring. The previous crop was potatoes on broken-up grass-land with the addition of cake and calcium superphosphate. The author delayed the autumn sowing until December 15, 1917 so as to see how sensitive the germ was to

(1) As regards the varieties Aurore and Marquis see R., June, 1918, Nos. 640 and 641. (2a.)

cold. Just after sowing the thermometer fell so low that germination only took place between January 8-15 and very irregularly. In spite of this delay the wheat did not suffer at all. It was even so vigorous that in April it was topped to avoid lodging which partly occurred on June 17 during heavy rain accompanied by wind. The amount of straw produced per acre increased to 5085 lb. per acre. The date of harvest compared with that of spring-sown Manitoba was only advanced 5 days.

The test of seed from two soils of different chemical composition only gave a slight difference in the yield.

Seed obtained from bearded ears gave yields distinctly higher than those from beardless ears (27.4 and 21.2 imp. bus. per acre respectively).

At the same time the author tested the varieties Kurrachee, of Indian origin, Aurore and Marquis.

The variety Kurrachee behaved very well. The stems were 31 in. high and gave square ears with black awns. The seed is red and elongated. This spring variety is hardy and seems worth propagating. The yield was 26.1 imp. bush. per acre.

The variety Aurore arrived too late and the yield was low on account of the drought (10.7 imp. bus. per acre). When sown in March it gave much more conclusive results in another experiment field. For the same reasons the Marquis variety yielded still less (6.9 imp. bus. per acre).

1350 - Cultural Tests with Sol II Wheat in South Sweden. — ÅKERMAN, Å., in the *Sveriges Utsädesförenings Tidskrift*, Year XXVIII, Pt. 3, pp. 121-124. Malmö, 1918. .

The Sol II variety of wheat, obtained from the cross Sol I  $\times$  Extra Squarehead II, is remarkable for the strength of its culms, its resistance to cold and early ripening which make it possible to sow (at the end of September) the seed which has just been gathered. The above cross was made in order to eliminate late ripening, the great defect of the Sol I variety. The seed of the same year, if sown immediately after harvest, germinate with difficulty, sometimes not at all, so that they have to be stored for some time to avoid these defects.

The new variety was tested in different localities in South Sweden, and the results obtained are given in the paper under review.

*Tornby Station* (near Linköping, Östergötland). — Below are given the average yields of the varieties tested for the period 1914-1917. The first figure shows the yield of grain in cwt. per acre, the second the relative index of productivity. Sol. I 31.37, 100; Sol II 33.72, 107.2; Bore 31.21, 97; Iduna 31.00, 99.1; Renodlad Squarehead 29.47, 94; Thule 1 30.22, 96.3; Thule II 31.61, 100.8.

*Svalöf Station* (Scania). — During the period 1916-1917 the Sol II variety gave good results but was inferior to the Pansar and Fylgia varieties. Sol. II 37.19, 105.1; Pansar 37.59, 112.5; Fylgia 36.47, 108.

*Ultana Station* (Uppland). — As the north is approached Sol II gradually loses its value; in cultural tests at Ultana it gave results much inferior to those of Thule wheat.

CONCLUSION. — Sol II is the type of wheat most suited to Östergöt-

land and the districts of Västergötland and the province of Bohus with similar weather conditions. Further south Sol II may be used wherever Fylgia wheat is not sufficiently resistant to the winter cold and where Pansar wheat is too late.

**1351 - Pansar Wheat in South Sweden.** — ÅKERMAN, Å., in the *Sveriges Utsädesförenings Tidsskrift*, Year XXVIII, Pt. 3, pp. 117-120. Malmö, 1918.

Of all the different varieties of wheat recently put on the market by the Swedish Seed-producing Society, the best is "Pansar" wheat, obtained by NILSSON-FHLE from the cross Kotte × Grenadier. Since 1915, when it was first put on the market, it has become gradually more and more popular on account of its high yield and good resistance to cold and rust. The winter of 1916-17 was a good test for resistance to cold; the Tystofte, Smaa, Vilhelmina, and even the Fylgia, varieties suffered more or less, whereas Pansar resisted and gave an excellent crop. This may be seen from the following comparative data; in each case the first figure represents cwt. per acre and the second the relative index of productivity as compared with that of native Swedish wheat ("Swenskt lantvete"), equal to 100: — Native Swedish wheat, 21.5, 100; Pansar 35.8, 167; Fylgia 31.8, 148; Tystofte Smaavede 26.0, 121; Sol II. 33.3 154; Sol I 31.1, 145; Extra Squarehead II 27.8, 129; Vilhelmina 13.0, 62. The low yield of the last variety is the result of its lack of resistance to cold.

The superiority of Pansar wheat is due, not only to its strength, but also to: — 1) its late ripening which enables it to benefit by the July rains; 2) the presence of a waxy covering on the leaves which regulates and modifies transpiration. These characters make Pansar wheat the variety best suited to Scania (provinces of Malmöhus and Kristianstad). It also gives good results in the provinces of Halland, South Kalmar, Blekinge, Öland, and Gotland.

**1352 - The Rational Distribution of the Different Varieties of Rye in Sweden.** — LUNGE W. E., in *Sveriges Utsädesförenings Tidsskrift*, Year XXVIII, Pt. 3, pp. 97-116. Malmö, 1918.

The comparative cultural experiments made at Svalöf and the branch stations since 1906 have shown which varieties of rye are best suited to the local weather and agio-geological conditions of the different provinces of Sweden. The most important results obtained are below: —

**SVALÖF 1907-1917.** — *Varieties tested:* — Stjärn and its line 0302, Schlanstedter and its line 0451, Frof. Heinrich and its line 0280, Petkuser, Probsteler and its line 0530, Bretagner and its line 0420, Wasa and selected Wasa, Midsschmar and its line 0590, native grey oats of Östgöta.

*Characters studied:* — Yield in grain and straw per acre, weight of a bushel of grain, weight of 1000 grains, strength of straw, shown by a number ranging from a minimum of 1 and a maximum of 10.

In all the tests taken together the Stjärn variety ranks first for yield with 34.4 cwt. of grain per acre and 55.4 cwt. of straw. In weight of grain (55 lb.) per bushel, resistance to cold and strength of straw (7.4), it is more

or less equal to Petkuser, the yield in grain of which is 6.9 % lower (32.25 cwt.). One of the few defects of Stiärn rye is the length of its culm which causes it to lodge easily. The author's attempts to isolate forms with short straw have already given good results. The stalks of line 0302 are from 2 to 3 inches shorter than those of the parent variety and also stronger (strength = 7.7 as compared with 7.4 for the original Stiärn).

Certain new lines (Nos. 0302, 0451, 0280, 0530, 0420) gave a yield in grain a little inferior to that of Petkuser. Line 0280 (of Prof. Heinrich) is remarkable for the strength of its straw (= 8). It is hoped to obtain good types of rye for central and northern Sweden from all these lines. The Danish variety Bretagner is inferior to the varieties Stiärn and Petkuser, with which it can compete in dry years only, in light, mellow land. None of the other varieties tested gave good results.

What has been said for Svalöf applies also to the provinces of Malmö and Kristianstad, as well as to those parts of the neighbouring provinces where the soil and weather conditions are similar.

**CENTRAL, SWEDEN.** — In the cultural tests made at the stations of Ultuna and Alnarp and the branch stations of Östergötland and Västergötland, the Stiärn variety, although followed closely by the lines 0302, 0451 and 0280, nevertheless took first place with 27.1 cwt. of grain per acre (compared with 25.7 cwt. for Petkuser). The native varieties Grey Rye of Östgöta, Ultuna, etc. were inferior in grain yield to Stiärn and Petkuser by 15 and 16 % respectively.

At Alnarp the Bretagner variety yielded a little more than Petkuser. This was the result of the great drought of 1916 which put to the proof its special resistance to drought.

**LOCAL CULTURAL TESTS:** — Tests were made in the provinces of Kristianstad, Östergötland, Stockholm, Upsala, Örebro, Göteborg, Bohus, Halland, Västmanland, Värmland, and in the Island of Gottland. In the first seven provinces the Stiärn variety ranked first and in the provinces of Västmanland and Halland better results were obtained with the Petkuser variety. In Värmland the Stiärn and Petkuser varieties were surpassed by selected Wasa rye and, in Halland, by the Bretagner variety. The native ryes (of Östgöta, Gottland, Göteborg, etc.) proved in every case inferior to the selected ones.

As the north and interior are approached the environmental conditions become less and less favourable to the Stiärn and Petkuser varieties which gradually lose their value and supremacy through their insufficient resistance to the severe winters, and are replaced by selected Wasa rye (e. g. in the province of Värmland). In the province of Stockholm and in Västerbotten common Wasa rye yields more than selected Wasa. In the cold districts of Norrbotten the local native types do best. This is shown by the following relative indices of productivity:

*In Västerbotten:* — Native Norrland rye 100, grey Östgöta rye 98.4, selected Wasa 110.2, common Wasa 123.4

*In Norrbotten:* — Selected Wasa 62.4, common Wasa 72, native Norrland rye 100.

2353 - Commercial Pulse Crops. — *Bulletin of the Imperial Institute*, Vol. XV, No. 4, pp. 503-544. London, October-December, 1917.

The chief leguminous plants that are cultivated chiefly for the sake of their seed in both tropical and temperate countries are: — *Arachis hypogaea* (Ground nut, earth nut, pea nut [U. S. A.], monkey nut, goober), *Cajanus indicus* (Pigeon pea or bean, Angola pea, Congo pea, Dál [India], Bombay tares), *Canavalia ensiformis* (Sword bean, over-look bean, cut-eye bean [W. Indies], horse beans [Montserrat], Go-ta-ni bean [E. Africa]), *Cicer arietinum* (Gram, Bengal gram, chick pea, Spanish pea, Garbanzo [Spain]), *Cyamopsis psoralioides* (Cluster bean, Guar bean [India]), *Dolichos biflorus* (Horse gram, Madras gram, Kulthi [India], *D. Lablab* (Indian bean, Lablab bean), *Ervum Lens* = *Lens esculenta* (Lentil), *Faba vulgaris* = *Vicia Faba* (Broad bean, Windsor bean, horse bean, field bean), *Glycine hispida* (Soy bean, soja bean), *Lathyrus sativus* (Chickling vetch, vetchling, grass pea, Indian pea, mutter or mattar pea, Khesari [India]), *Phaseolus aconitifolius* (Moth bean), *Ph. angularis* (Adzuki or Azuki bean [Japan]), *Ph. calcaratus* (Rice bean), *Ph. lunatus* (Lima or Duffin bean, Rangoon bean, Madagascar bean, butter bean), *Ph. Mungo* (Black gram, Urd [India]), *Ph. radiatus* (Green grain, Mung [India]), *Ph. vulgaris* (Dwarf bean, French bean, Kidney bean, haricot bean), *Pisum arvense* (Field pea, grey pea, dun pea, partridge pea, maple pea, blue pea, Bara mattar [India]), *Pisum sativum* (Common or garden pea), *Vigna Catjang* (Black-eye cow pea, cherry bean, cow pea, Chowlee, Lobia [India], Tow Cok [China]), *Voandzeia subterranea* (Bambarra ground nut, Mozambique gram, Madagascar earth nut). Although eaten as pulses in the countries where they are grown, ground nuts and soy beans are valued in Europe chiefly as oil seeds and they will therefore not be dealt with in this article.

*Canavalia ensiformis* (sword bean), *Cyamopsis psoralioides* (cluster or Guar bean) and *Voandzeia subterranea* (Bambarra ground nut) are of importance only in the countries where they are produced; they are, however, of value as food for man or for animals and a market for them may eventually be developed in Europe. Samples of "sword beans" from the Gold Coast, Honduras, Montserrat and Burma have been examined at the Imperial Institute, and no deleterious constituents were found in them, although they are considered to be harmful in some countries where they are grown, apparently on no very good grounds. Recently a variety of this species, called Go-ta-ni, has been received from British East Africa. Lablab beans are largely grown in China, India and other tropical countries. The Bambarra ground nut has also been examined at the Imperial Institute, and although no harmful constituents could be detected, it was not highly valued by merchants at that time (1909 and 1914). The great drawback to these pulses is that they are not known, and it is always difficult to find a market for them. The scarlet runner bean (*Phaseolus multiflorus*) is grown mainly for the sake of its green immature pods, but the ripe seeds are also eaten.

‡ The most important pulses commercially are the various kinds of peas and beans. The chief countries that export peas in normal times are India,

Russia, Japan, China and the Netherlands; those exporting beans are China, India, Turkey, Russia and Egypt. The trade of the United Kingdom in pulses is normally sharply divided into two sections:—1) for human food; 2) for cattle food. The first section includes:—haricot beans, white and coloured (*Phaseolus vulgaris*); Madagascar butter beans, Lima beans and Rangoon white beans (*Phaseolus lunatus*); green peas, smooth and wrinkled varieties (*Pisum sativum*); yellow peas, smooth and wrinkled (*Pisum sativum*); field peas (*P. arvense*) split or ground into meal or flour; chick peas or Spanish peas, white kinds (*Cicer arietinum*); lentils, whole or split (*Lens esculenta*); Japanese "Adzuki" or Chefoo red beans (*Phaseolus angularis*); other small beans produced by *Phaseolus* sp. The second section includes:—dun peas, maple peas, partridge peas, grey or field peas (*Pisum arvense*); broad beans and horse beans (*Vicia Faba*); pigeon peas or beans (*Cajanus indicus*); horse gram (*Dolichos biflorus*); Bengal gram or chick peas, coloured kinds (*Cicer arietinum*); all other kinds of coloured beans, including red Rangoon beans (*Phaseolus lunatus*). Various kinds of beans are known in British commerce as haricots, including the seeds of *Phaseolus vulgaris*, to which the term is more correctly applied, and the seeds of certain varieties of *P. lunatus*. Butter beans are furnished by other varieties of the same species.

*Phaseolus vulgaris*. — Before the war British supplies of true haricot beans were obtained chiefly from European countries especially Rumania, Germany, Belgium, Italy and France. These beans were chiefly white — "White Italian", "White Soissons", "White Danubian" — but coloured varieties "Rose Cosos" (speckled), "Canadian Wonder" (purple); "Burlotti" (speckled) were also imported. Since the war the Royal Horticultural Society has imported from Holland the "Dutch Brown" bean, of a light coffee-brown colour, and said to be superior in flavour to the white forms. In tropical South American countries beans form to a great extent the staple food of the people and are grown in large quantities. Before the war these countries had to import beans, but the last few years they have become exporters. Thus Brazil, in 1914 only exported 4441 kg., while, in 1915, 276159 kg., and, in the first 5 months of 1917, 53084'331 kg. were exported. Since the war Japan has also begun to export considerable amounts of haricot or kidney beans, that are either produced locally or imported from Manchuria, North China and Korea.

*Phaseolus lunatus*. — Originally native to South America, *P. lunatus* was introduced to Southern California as early as the fifteenth century, and is now widely cultivated throughout the warmer parts of the world. It was introduced into Madagascar about 1864, and since the French occupation it has become an important article of export. Madagascar traders wrongly call these beans cape peas or Pois du Cap, while on the London market they are called "butter" or Madagascar beans. In 1914, 8561 metric tons were exported, about 7 times more than in 1906 (1).

Forms of *Ph. lunatus* are largely grown in Burma. The two most com

(1) See R., March 1918, No. 291. (Ed.)

mon forms grown in Burma are the red-seeded and the white-seeded kinds, known commercially as "Burma red beans" and "Burma white" or "Rangoon" beans and locally as Pé-gya and Pè-byu-galè. In 1916-17 Burma exported 1 439 009 cwt. of pulse mostly to the United Kingdom. The Imperial Institute has sent to Burma samples of Madagascar butter beans for trial; the local Department of Agriculture are testing other white beans. The cultivated forms of *P. lunatus* from Madagascar, South America and Burma and probably also from the United States and Southern Europe rarely if ever yield hydrocyanic acid in quantities likely to be injurious. On the contrary that acid has been found in beans from wild plants in Java and Mauritius; for these reasons importations from new areas should be examined before being placed on the market.

In 1916 the United Kingdom imported 1 077 600 cwt. of haricot beans as against 313 063 cwt. in 1913. Since the war the imports of this bean are mostly from India (over  $\frac{7}{10}$  in 1917) followed by Madagascar and Japan.

*Small-seeded Phaseolus*. — The "azuki" bean (*P. angularis*) of China and Japan, "mung" (*P. radiatus*), "urd" (*P. Mungo*), "moth" (*P. acutifolius*) of India, and the "rice" bean (*P. calcaratus*) of India and the Far East are of great value as food-stuffs in the countries where they are grown, but are little known in Europe save as feeding-stuffs for cattle. *P. angularis* has been grown experimentally at the Arlington Farm, Virginia, U. S. A., with favourable results. Owing to its value for making flour or paste it should be tried wherever the haricot grows.

*Vicia Faba*. — The chief varieties grown in the United Kingdom are the following: — Heligoland bean; horse or tick bean; Scotch horse bean; winter field bean; early Mazagan bean; Long-pod bean; broad or "Windsor bean". The field bean is a common crop in Europe, and is largely grown for export in Egypt, Turkey and China. In 1916 the United Kingdom imported 1 110 605 cwt. of beans other than haricot beans. Before the war China, Germany and Turkey supplied a large proportion of the imports, but in 1915 more than half of the total import was obtained from British countries, British India and Egypt having increased their exports. A table gives the world's production of beans (area and crops) for 1910, 1911 and 1912; another gives that of peas.

Peas (*Pisum arvense* and *P. sativum*). — In 1916 the United Kingdom imported 981 331 cwt. of peas as against 2 464 607 cwt. in 1912. Before the war peas were chiefly supplied by India, New Zealand, Germany, Holland, Japan; since the war Japan and China have increased their contributions.

*Lathyrus sativus* (mutter peas.) — This is cultivated throughout India where it is known locally as Khesari. From Mediterranean countries the whiteflowered form has been introduced to Canada, where it is known as the "grass" pea, and is produced on a fairly large scale in Ontario. These peas have a high protein content but some forms are said to have poisonous properties which cause the disease known as lathyrism (paralysis of the lower extremities in man and animals) as a result of their continued use

as food. In India they are eaten by the poorer classes on account of their abundance and cheapness. The nature of the toxic substance causing lathyrism is not known. Seeds of forms obtained from India, Cyprus and Canada have been examined at the Imperial Institute with a view to the isolation of a toxic constituent, but with negative results. Investigations were conducted at the Agricultural Research Institute, Pusa, on samples obtained from Barail, a village near Pusa, which is notorious for cases of lathyrism, and the Central Provinces, where the disease also occurs, and it was found that samples of Khesari were often contaminated with seeds of *Vicia sativa* and *V. hirsuta*, from which a cyanogenetic glucoside was isolated. It is possible, therefore, that the harmful properties attributed to the seeds of *Lathyrus sativus* may in some cases be due to obnoxious impurities. Experiments conducted in Canada with Canadian grown *L. sativus* peas as food for fowls gave good results and no harmful effects were observed. It has been found that lathyrism only occurs in man when *L. sativus* peas form almost the sole diet. There is now much evidence in favour of the view that the use of any one kind of grain, even wheat, as the sole diet may lead to harmful results.

*Vigna Catjang* (Cow peas). — There are 2 varieties, the bushy (var. *typica*) and trailing (var. *sinensis*), both grown in most warm countries. For use as pulse the white or blotched forms are preferred; they are much eaten in Burma, and are appreciated in the United States and to a smaller extent in the United Kingdom.

*Lens esculenta* (Lentils). — Largely consumed as human food in Europe as well as in the East. In English commerce two forms are met with, "French" and "Egyptian"; the former are large, ashy-grey externally, yellow inside, and are usually sold entire; they come chiefly from Russia and Germany; the latter are small brown, with an orange-coloured inside and are usually sold "split"; they come chiefly from India. In 1915 the United Kingdom imported 329 870 cwt. and in 1916 143 960 cwt. of lentils.

*Cajanus indicus* (Pigeon pea). — Two forms are grown, and some authors have made them species. One form has yellow flowers (*C. flavus*) and usually only 2 unspotted seeds in each pod; the other (*C. bicolor*) has yellow flowers streaked with reddish purple and pods containing 4 or 5 seeds which are usually spotted or streaked. Experiments made at the Labour Farm, Bihar and Orissa, between 1908 and 1911, proved that the tall erect form (*bicolor*) was the superior and best suited to local conditions. It is cultivated in most tropical countries. In Bombay it is known as tur, tuer, togari, in Bengal as arhar or rahar; in Africa as the Congo pea, Congo bean or Angola pea; in the West Indies it is called no-eye pea, and in Mauritius and the Mascarene Islands it is known as ambrevade. It is also grown in Southern Rhodesia, Madagascar and Australia. The pigeon pea is largely used in India for human food, and as fodder for horses and other animals when the crop is plentiful.

*Cicer arietinum* (Gram or Chick pea). — It is grown in most parts of Southern Europe, particularly in Spain; in northern Africa, chiefly in Mo-

rocco ; in Asia, particularly in India, and in Mexico. About 500 000 acres are devoted to this crop in Spain, where the average production is estimated at 100 000 tons. In India the average area under grain for the 5 years 1909-10 to 1913-14 was about 15 million acres, with an average annual out-turn of about 3 million tons.

Experiments have recently been made at Pusa with a view to improving the types of chick peas grown in India, and 2 types have been selected, one producing a small whitish seed and the other a small reddish-brown seed. The former gave an average yield for 4 years of 1 600 lb. of seed per acre and the latter an average of 1 666 lb. for the same period.

The Indian chick peas are smaller than those of Europe, and are usually of a dark brown or reddish-brown colour ; they are chiefly used as food for cattle in the United Kingdom, but in India they constitute one of the staple foods of the people, being eaten either parched or boiled or ground into meal. Gram and barley roasted and ground into meal is known as "su too" and is sold in all Indian bazaars. Gram is much esteemed as a food for horses in the East ; it is, however, seldom given alone, but forms part of crushed foods. India furnishes most of the gram required in Europe ; in 1911-1912 India exported 6 934 840 cwt. and in 1916-17 761 930 cwt. of gram and forse-gram (*Dolichos biflorus*) ; the latter is grown chiefly in Southern India and shipped from Madras, the amount exported annually for the period 1911-12 to 1916-17 being 12 578 cwt.

*Composition and food value of pulses.* — The article concludes with a table showing the chemical composition of 21 pulses. If eaten in moderate quantities and properly prepared they are almost as digestible as other vegetable foods, but although pulses contain, weight for weight, as much protein as meat, they have not an equal food value as regards the nitrogen, since the proteins of meat are more readily absorbed than those of leguminous seeds.

1354 — *The Production of Tapioca in the Dutch East Indies.* — *Handelsberichten*, Year XII, No. 600, pp. 349-351. The Hague, 1918.

STARCH CROPS

The cultivation of manioc (*Manihot utilissima* Pohl), from whose starchy root tapioca is produced, has only recently been developed in the Dutch East Indies, although, already in 1854, official initiatives were taken. The aim of the Government was to provide the native with an "auxiliary food stuff" with the object of guarding against the lack of ordinary foods, especially rice, in times of famine. The population required several years in order to appreciate the utility of this crop, which now is fairly well diffused. The analysis of the manioc roots, made at the Laboratory of the Colonial Museum at Haarlem, gave the following results for fresh and dry samples respectively : — nitrogen, 0.26 and 0.50 % ; albuminoids, 1.63 and 3.30 % ; fats, 0.94 and 1.90 % ; carbohydrates (expressed as starch), 39.79 and 80.60 % ; crude fibre, 2.10 and 4.25 % ; ash, 0.24 and 0.48 %. The fresh sample contained 50.63 % of water.

The native population eats the roots as they are — skinned, then cooked or boiled — or mixed with other ingredients. The product for export is

prepared in works, now very common, especially in Java. In this way are obtained: — 1) manioc or cassava flour ("tapioca-meal"); 2) those products, prepared under another form and higher priced, called "tapioca perlé" and "tapioca flake". The dried manioc roots and the by-products obtained in preparing the flour are also exported. The exports are mostly towards the United Kingdom, the United States and the Netherlands. The number of metric tons exported from 1915 to 1917 are given below.

Products	Destination	1915	1916	1917
Manioc flour . . . . .	Netherlands . . . . .	7 279	79	227

## FIBRE CROPS

1355 — The Possibility of Developing Cotton-growing in Cambodia. — DE FLACOURT, in *Congrès d'Agriculture coloniale*, Gouvernement général de l'Indochine, Saigon Series, Bulletin No. 5, 29 pp. Saigon, 1918. Review in the *Bulletin économique de l'Indochine*, Year XXI, No. 129, pp. 235-262. Hanoi-Haiphong, March-April, 1918.

Cotton is widely grown in Cambodia, along the banks of the Mékong and its chief tributaries, from Kratié to Banam, and along those of the Bassac, especially in the provinces of Saang (Residency of Kandal) and of Loenk-Dek and Prey Krabas (Residency of Takev). It is grown on a large scale and throughout the country it is grown sporadically round the huts, even in the most remote and difficult accessible districts.

VARIETIES. — Cambodia has four distinct varieties of cotton: —

1) "Krabas" or "Krabas bay" (*Gossypium hirsutum* L.) (1), of Ame-

(1) The Cambodian term "Krabas" (pronounced "Kreba" means raw unginned cotton, and has been extended to the cotton plant itself. This plant has hitherto been considered as a variety of *G. herbaceum* L. In this the duration of the vegetative life of the plant seems to have been taken into consideration far more than its actual characters. In Cambodia this cotton is annual, but it is the special cultural conditions to which it is subjected that make it so. Grown on banks flooded as soon as the waters fall, it naturally disappears when the waters, which cover all the flat country for 3 or 3 months, rise again. In the *Bulletin économique de l'Indochine* (p. 946, 1915) the author described it as a native type of the hirsute variety. (Author).

rican origin, usually known by the name of "Cambodian cotton". This is the only variety largely grown along the banks of the Mekong and the Bassac and their principal tributaries. It is the "Cambodian cotton" of India, where it was introduced some years ago and has been grown with good results.

2) "Krahan Tés" (*G. acuminatum* Roxbg.).

3) "Krabas Sàmrê" or "K. Sangkê", a type intermediate between *G. arboreum* L. and *G. indicum* Lamk. According to a determination verified by M. VIGUIER (Lecturer in Colonial Botany at the Sorbonne) it should be referred to *G. arboreum*.

4) "Krabas Sampau" (*G. arboreum*), found in 1915 in the Department of Siêm-rêap; it has not yet been definitely determined.

The last three types are only met with absolutely sporadically. They were introduced very long ago, probably from India, whereas the Cambodian *G. hirsutum* seems to have been introduced a relatively short while ago, doubtless directly from America. This last is the most important of the four types of Cambodian cotton, both with respect to the acreage over which it is grown and the large quantities of cotton it yields, giving rise to a brisk trade. In his report the author deals only with this *Cambodian type of hirsute cotton*.

The native crops are concentrated on the banks of the large river and principal watercourses (Chamcar) (1). They cover annually approximately 32 000 to 45 000 or 50 000 acres, according to the year, as the area cultivated varies with the height of the floods. As, in these soils cotton has to compete with other plants it is not possible to extend its cultivation much, the area of the banks being limited. Were it possible, by strong dikes, to protect from floods all the flat country behind the principal watercourses which form vast basins, the area over which cotton could be grown each year would be considerably increased. The best cotton lands in the State of Mississippi, U. S. A., were obtained by this method.

During the last six years the production of raw cotton in Cambodia was, in round figures:— 1912, 7 000 metric tons; 1913, 6 000; 1914, 8 000; 1915, 3 000; 1916, 5000; 1917, 5000. Most of the crop is ginned at the Khsach-Kandal works, and nearly all of it (except the 500 to 600 metric tons held back each year by the natives for sowing) is exported to Japan through Saigon, either directly or by way of Hongkong. The above figures show that the yield varies greatly from year to year. This is because, situated on the banks of the water-courses the native crops are cultivated at bad seasons. All the flat country is flooded by the Mekong (the floods of which are perfectly regular in duration) and it is impossible to choose the best time for sowing. The seed is sown as soon as the floods subside regularly and there is no more danger of their return. This occurs between the end of October and the beginning of December, and coincides with the end of the rainy season. Under these conditions the crops must depend large-

(1) The soil of the banks covered periodically by the floods are called "Chamcar" in Cambodian. (Author).

ly on chance. The relatively cold winter of Cambodia is early and if rain is more abundant than usual in March, April and May, the crop may be compromised.

These conditions also cause the fibre to be short (18 to 22 mm. at the most), irregular, woolly, and covered with small lumps caused by numerous completely atrophied seeds.

Attempts have been made to adapt cotton to soils sufficiently high to be completely free from floods. There is a considerable extent (19 768 000 to 247 110 000 acres) of such land in Cambodia. They are mostly low tablelands, slightly raised valleys or large plains. The experiments were started at the end of 1913 and, after four years, showed beyond doubt that the Cambodian cotton plant adapts itself very well to these lands and gives in them a better quality fibre (less woolly, more regular, without small lumps, on an average 24 to 29 mm. long), thus showing it is better suited to them.

Samples of cotton obtained from the first cultural experiments were sent to the Jardin colonial in August, 1915. These samples were examined by several experts, traders and manufacturers at Havre. The cotton was judged well suited to the French industry whereas, to use to the best advantage that obtained from "Chamcar" crops it would be necessary to modify or replace the machinery in French factories.

The author describes cultural tests made in red soil, soil of volcanic origin in layers of an average depth of 49 to 59 feet, purely vegetable, very permeable, but always cool, owing to the clay it contains. This soil covers an area estimated at 4 942 200 acres at an average altitude of at least 190 to 410 feet. During the experiments an average yield of 569 lb. of raw cotton per acre (without addition of fertiliser and without irrigation) giving 164 lb. on ginning was obtained. The yield of carded raw cotton was 34 %. The author estimates that the lands of Kompong-Cham and Kratié (1 482 600 acres), which offer a vast field for European and native colonisation will, when made fully productive, give an annual yield of more than 40 000 metric tons of carded cotton.

The improvement of the hirsute cotton of Cambodia by methodical selection is being undertaken by the local Agricultural Service, and, in spite of the difficulties due to present conditions, is almost accomplished. This, by multiplying the improved pure types, will make it possible to obtain a yet better yield of carded cotton.

One of the vital questions affecting the intensification of cotton production is that of the ginning industry and, to a lesser extent, that of the extraction of cottonseed oil. It is essential that the producer may be able to dispose of his crop, both immediately and progressively, at a remunerative price. The French cotton industry has too great an interest in this question not to give it full attention. The Association cotonnière coloniale especially has often interested itself in Cambodian cotton and is, therefore, in a position to do for Cambodia what it has done for West Africa, with a greater prospect of success.

The questions discussed above have attracted particularly the attention of the Chief of the Colony. No other crop is more suited to inclusion

in the economic programme of Indo-China than is cotton by reason of its rapid growth, great value of its product, and the ever-increasing necessity of freeing France from the onerous conditions of the foreign market.

1356 - The Deterioration of Egyptian Cottons and Means of Remedying it. — MOSSÉRI, V. M., in the *Bulletin de l'Union des Agriculteurs d'Egypte*, Year XVI No. 124, pp. 53-79. Cairo, August-September, 1908.

While it is incontestable that the qualities of the Egyptian cottons, especially those of the old varieties, have deteriorated of late years, opinion is very divided as to the causes of such deterioration. According to the theory most generally accepted at present, the Egyptian cottons are suffering from a degeneration which has considerably reduced their yield and hardness. Become more weakly, the cotton plants are more sensitive to bad weather and less resistant to the attacks of insects and other parasites. The very great spread of the pink bollworm (*Gelechia gossypiella*) appears to be owing to this degeneration.

As regards the pink bollworm, so far no type of cotton has been found that really has a natural or acquired immunity protecting it from the attacks of this insect, any more than from those of its other pests. The author hopes that this will be attained by selection. In fact, in India, the pink bollworm is a secondary pest; and, every time that Egyptian varieties have been introduced into that country, they have been literally ravaged while Indian cottons grown close by hardly suffered at all. It appears that Indian cottons have a certain natural immunity in this respect, probably of a histogenous nature, since MAXWELL-LEFROY attributes the resistance to a more abundant resinous gummy secretion in the valves of their capsules. This immunity is the result of a natural selection which may some time take place in the case of Egyptian cottons and thus protect them from this terrible pest.

But in the meanwhile, other means of control must not be neglected such as cultural, biological or technical methods the chief among which are the removal and subsequent burning of the capsules remaining after the last harvest, the collection of the capsules fallen on the ground and their burning, the treatment of the seeds so as to kill any larvae they contain, the growth of early varieties and the use of methods of cultivation so as to hasten, or to avoid the slightest retard in, maturity.

Experiments were carried out in 1916 and 1917 by the Minister of Agriculture in order to study the means of hastening maturity by the judicious use of pinching and removal of the leaves combined with a gradual reduction in the quantity of water supplied after the month of July. The results obtained along these lines seemed encouraging (1). It was found that the intensity of the attack of the pink bollworm does not in any way depend on the age of the Egyptian varieties, nor on their degree of purity or degeneration; if there is any degeneration.

The author denies any such degeneration and attempts to prove that

(1) *The Agricultural Journal of Egypt*, Vol. VII (1917), pp. 120-135. (Author)

the Egyptian cottons have undergone a *deterioration* of late years and not a degeneration in the strict sense of the term.

The *quantity* and *quality* were affected:— 1) in the quantity (yield) the deterioration showed under the effect of *accidental* causes; 2) in the quality, it was shown by *essential* causes.

The accidental causes are due to the environment and their effects come under the heading of "fluctuation" and are not permanent.

The essential causes are due to the constitution of the plant, i.e., to the way in which it reacts to the environmental conditions; their effects are permanent.

The author only deals with the *quality*. The essential causes are the most important and originate in the impurity of the type grown. The most efficient cause of this impurity lies in the natural or artificial crossings to which Egyptian cottons have been or are still the object. This hybridisation is chiefly due to growing several varieties side by side or to the use of seed containing a mixture of different types. The remedies are clear: isolate and purify the cultivated varieties or seek better ones, multiply them and propagate them without it being possible to contaminate them. Three methods have been suggested.

1) The first was begun by BALLS in the laboratory of the Khedival Agricultural Society, now the Sultanian Agricultural Society (1). It consists essentially in isolating a well determined type of pure strain, then, by crossing and methodical elimination, adding to the chosen type the advantageous specific characters that are required. This may be called the *addition* or *synthetic method*.

2) The second consists in annually isolating and selecting a certain number of plants showing the required specific characters. By repeated elimination of plants lacking the desirable characters the cases of atavism throw-back to an undesirable type are diminished more and more in the progeny. This may be called the *analytic* or *elimination method*.

3) The third method is that of the *selection* of advantageous variations.

The ideal solution of the durable and permanent improvement of Egyptian cottons can only be obtained by applying the remedies quoted above. There is no great difficulty in purifying the cultivated types, and the multiplication of pure seed is also fairly easy. But the propagation of such seeds free from the possibility of any future contamination constitutes the most delicate task for the moment. It is, however, an essential condition, as is shown by the excellent results obtained in the United States by the rigorous application of these principles. The author recalls the work done in this direction in the United States, especially in Arizona (2).

The author thinks that to resolve the problem, if not radically, at least as satisfactorily as possible, an organisation should be created under the aegis of the Government, a sort of *permanent Commission* in which all those interested in any way in the production of Egyptian cotton

(1) See R., August, 1915, p. 1017. (Ed.) — (2) See R., May, 1916, No. 518. (Ed.)

— producers, brokers, spinners, etc. — should be fully represented by their most competent elements. This organisation would take the question in hand, with the widest possible powers, and would follow a programme, the outline of which is given by the author as follows : —

1) Divide Egypt into zones of different climates ; create in each zone a chief station, with sub-stations should the type of soil require it, to undertake : —

a) the purification of the existing varieties or the creation of better ones by using one or another of the three methods given above, or, better still, simultaneously by all three methods ;

b) repeated tests to ascertain the varieties most suited to each zone;

c) the scientific study of the cotton plant ; in this it would probably be possible to collaborate with the powerful association (Cotton Research Association) now being formed in England to investigate scientifically in all the British Empire all the problems concerning the cotton industry.

2) Propagate the pure strains on land attached to these stations preparatory to multiplying them later on larger areas depending on, or rented by, the station, or cultivated by the owners under the direct control of representatives of the Permanent Commission.

3) Ginn the different types undergoing selection in machines belonging to the station.

4) Forbid the cultivation of several varieties side by side and only allow the cultivation in each zone of one of several varieties of those found the most remunerative, allotting one or more special works to each zone for ginning.

5) Inspect the fields to eliminate plants not true to type, etc.

6) Control and regulate the sale and distribution of the seed.

7) Forbid the propagation of a new variety until repeated cultivation tests in the stations controlled by the Commission have indisputably shown its superiority over the corresponding type already cultivated. These tests would be made on isolated areas so as to avoid any contamination.

Pessimistic conclusions should not be drawn from what has been so far said, for the future may be faced with confidence and for a long time still Egypt will occupy the first rank among countries producing fine, long staple cotton. Even now, in spite of the sensible decrease in its cotton production Egypt always holds a preponderating place. In fact, whilst America produces 100 000 bales of Sea-Island cotton and hardly 6000 bales of the Egyptian type of cotton. Egypt still furnishes more than a million.

Egypt could have profited by this supremacy had its cotton market been better organised. This would also be a task for the Permanent Commission the organisation of which is urged by the author.

1357 — **Four Large Scale Textile Crops : Jute, Crotalaria, Hibiscus, Sesbania, with a Note on Abroma.** — HAUTEFEUILLE, L., in the *Congress d'Agriculture Coloniale, Gouvernement général de l'Indochine*, Hanoi Series, No. 5, 65 pp. Hanoi-Haiphong, 1918.

The tests of textile plants carried out by the author on behalf of the Indo-Chinese Administration as the result of a mission to India in 1904 regard Tonkin and were spread over 8 or 9 years. They include ramie, jute,

the textile *crotalaria*, *Hibiscus cannabinus*, *Sesbania aculeata* and *Abroma augusta*. As ramie was worth dealing with separately (1) the other five plants are dealt with in the present study.

The utility of these tests is shown by the different conclusions to which they lead and which the author summarises as follows : — *Hibiscus cannabinus* seems unable to become suitably acclimatised to Tonkin; *Abroma augusta* will not grow healthily in dense plantations; *Sesbania aculeata* should do well in the alluvial, damp parts of the Tonkin delta; *Crotalaria juncea*, already tested at Hué and near Hanoi, is very hopeful and may prove a crop worth introducing into the country; jute, although finding in Indo-China less favourable conditions than those in British India may play, especially in Annam and Tonkin, on certain reduced points, an appreciable part.

1) JUTE. — This is the French and English name for two species of *Corchorus* — *C. capsularis* and *C. olitorius*. Jute is probably the most important textile fibre after cotton and hemp. According to WIGMAN (*Revue des cultures coloniales*, December, 1902) the annual production of British India amounted to about 1 476 300 tons and, at that time, Calcutta exported 100 million gunnies. Indo-China imports about 10 million such sacks which might well be made locally. All the jute, manufactured or not, comes from Bengal where the crop covers at least 24 700 000 acres. The idea of cultivating jute in Tonkin suggests itself naturally, as there is much analogy, generally speaking, between Bengal and that colony; the two deltas of the Ganges and Red River are mostly alluvial, abundantly provided with water; the climatic conditions are similar, labour is plentiful and easily satisfied. Ponds and watercourses are numerous in both countries, which is necessary for retting. The water communications help economically in the carriage of the bulky material. This material can be manufactured on the spot or exported through easily accessible ports. There are, however, sufficient differences between the two countries to call for caution; in particular, the distribution of the rainfall is less even in Tonkin than in Bengal.

The author considers in turn the species and varieties of jute (the two species only seem to include about 40 varieties, the species *capsularis* having 30 and the species *olitorius* 10), the requirements and peculiarities of its cultivation, the experiments carried out at La-Pho, the yields per acre, and the cultural and economic possibilities of jute in Indo-China.

The yields of well-dried fibre, obtained in the La-Pho experiments were : — 729, 923, 942, 892, 1 020, 1 030, 1 168, 1 236, and 1 275 lb. per acre. These yields are decidedly lower not only than those given by specialists, but also than those obtained at the Burdavan Experiment (Bengal) Farm, which reached as much as 2 641 lb. per acre. The highest yield obtained at the Phu-Thy Experiment Station was 1 445 lb per acre.

The highest monetary return obtained by the author (total return, not profit), was 61.75 \$ per *mau* (2) and the smallest return 50 \$, taking

(2) The *piastre* (\$) is worth about 2 s. at *par*; the Annamite *mau* equals 38750 sq. ft. (Ed.)

jute at 12 \$ per 220 lb. At Phu-Thy 70 \$ per *man* was obtained. It may be said that the native gets a return of from 30 to 35 \$ from a *man* of land cultivated with jute. To obtain this, the expenses must not exceed those for maize or beans; the native and his family have simply to pay more attention to the crop. The choice of the moment for preparing the soil and sowing requires more care than for other crops. The operations of harvesting, cutting, retting and baling jute are more heavy than for any other crop. The author thinks this is the only consideration to take into account with the gross yield.

Although jute growing does not pay for European colonists, its growth by natives would only be possible when it is encouraged and supported for some years by the European colonists, who would act as bankers and exporters. In the future the help of the European colonists will probably be able to be dispensed with as the natives become more enterprising and less sedentary when, with them or by their help the intensive agricultural occupation of Central Tonkin will be undertaken.

II) CROTALARIA (*Crotalaria juncea*). — This papilionaceous legume is largely grown in British India for its fibre, which is treated locally and exported to Europe under the name of "Sunn hemp". Though inferior to jute it is very useful in mixtures. It is the only crotalaria cultivated out of the 30 species belonging to the Bengal flora. It is used for green manuring and its leaves and seeds are fed to live stock.

M. LEMARIÉ, at Heré, has been interested in this non-exhausting, but probably improving plant (owing to nitrogen-fixation by its root nodules), which is grown over such large areas in India that it may be inferred that the plant is not difficult and does well in varied soils and climates. He was aware that it can be harvested and defibrated more rapidly than jute and that it can more easily be introduced into crop rotations as it grows and flowers all through the year. According to the literature on the subject, a crotalaria requires less care than other crops.

The La-Pho experiments on *Crotalaria juncea* were not as ample as was necessary, but they have shown that it gives good and very regular yields in Tonkin; few crops are so easy and safe. Its growth and harvesting are always sure with the minimum of work: — ploughing once, harrowing once, no weeding, prompt retting, easy defibration, the possibility of harvesting after 75 days or leaving the crop standing without serious harm.

The financial return is low and the crop does not always find a ready sale. In fact 624 to 714 lb. of dry commercial fibre per acre, at 27s. 9d. per 220 lb. gives 58.3 s. and 90s. per acre or 35 to 40 \$ per *man*. But this is the maximum; the minimum yield of 446 lb. per acre or 25 \$ per *man* must be taken as a basis for calculation.

These are fairly good yields and would satisfy the native, considering the small amount of work sunn hemp requires; but they would not suffice for European colonists working directly. In order to encourage the natives to grow crotalaria, a fibre market should be established in Tonkin.

III) *Hibiscus cannabinus*. — From tests made at La-Pho and Bat-Bat

(Tonkin) it was found that *Hibiscus cannabinus* or Deccan hemp (1) or one of its varieties or varieties of *Hibiscus Sabdariffa* (or "Roselle hemp") may be of interest as a crop for Tonkin and, better still, Annam, in order to provide a fibre for local needs, especially in the mountain region. But it is not the moment to anticipate an important yield, not only on account of the cultural requirements of this Malvaceae, but especially because, in the Delta and Central regions, it does not fit in with the crop rotation:— if it is to follow a maize crop it cannot be harvested in time to follow it by rice.

• (V) *Sesbania aculeata*. — Leguminous plant also known as *Aeschynomene spinulosa*. This crop, which furnishes the "dunchi" of Bengal, may be grown in Tonkin in the future. It is a fibre for low, damp soil, and its growth, like that of *crotalaria*, is always sure in Tonkin with encouraging regularity; it has, moreover, the advantage of not being exhausting. But its fibre is inferior to that of jute and at present is only of interest for mixing with jute. The author thinks this fibre is not used alone industrially. *S. aculeata* gives fine crops in Tonkin and grows to a size there that helps it to resist passing floods.

V) *Abroma augusta*. — This Sterculiaceae plant produces a fine fibre, but does not enter easily into large-scale cultivation. It has to be grown suitably spaced, for as it branches greatly, it cannot be crowded, so as to obtain big and paying yields. In 1917, 3 plots of 300 sq. metres each, one 1 metre apart, the second 50 cm. apart, the third 35 cm. apart, gave respectively:—1) 95 kg. of green material = 3.56 kg. of well dried fibre, or 3.75 %; 2) 40 kg. of green material = 1.05 kg. of well dried fibre, or 2.64 %; 3) the third plot was very bad. Grown under suitable conditions *Abroma augusta* does not yield 178 lb. of fibre per acre.

So that the new trials might be justified, the price per kg. of the fibre would have to be 3 francs which, in spite of the beauty of the fibre, is not probable, unless some special use for it is discovered.

1358 — **Observations on Ramie in Indo-China.** — HAUTEFEUILLE L. in the *Congres d'Agriculture coloniale*, Gouvernement Général de l'Indochine, Hanoi Series, No. 4, pp. 51. Hanoi-Haiphong, 1918.

In his report to the Congress of Colonial Agriculture the author throws light on the ramie question as regards the exclusively cultural point of view. He has followed all that has been done on the subject of ramie for the last 40 years with the greatest attention. In this work he has collected and condensed all that has been published on the question in all the world as well as his own papers (especially in the *Bulletin économique de l'Indochine*, No. 115, September-October, 1915) containing data never before published and his personal observations. His work is, therefore, very complete and of decided importance for all those interested in the ramie question.

The author considers successively and in detail the requirements of ramie as regards soil, climate, manuring, depth of ploughing, permeability of the soil, effects of drought, sun and heat, irrigation, plantation, hoeing

(1) It is the "da" or "dah" of French West Africa. (Ed.)

and weeding, cutting, duration of a plantation, yield in fibre, presence and disadvantages of gum, treatment of the crop. He then describes experiments carried out at La-Pho (Tonkin). These experiments were insufficient but gave some results which are duly recorded.

**SPECIES AND VARIETIES.** — There are 4 ramies: — white ramie (*Boehmeria nivea*), green ramie (*B. utilis* or *Urtica tenacissima*) and two that have been found at Laos or Yunnan, one red, the other yellow. There are no striking differences in the general appearance in full growth of the various ramies, at least as regards the height. The observer must walk down the lands in order to see differences which regard mostly the number and thickness of the stems and the thriving appearance. The foliage of green and white ramie is always denser, with larger and darker leaves. The stems of yellow ramie are generally weaker than those of other ramies. As regards the number of stems the red and yellow were equal, while being inferior in this respect to the two others. This did not hold true at the beginning and end of summer. Winter has a depressing effect on all 4 ramies. The green species is persistent and the white is deciduous. This is very characteristic of white ramie, and less so of the red and yellow ones. But green ramie, if it is not deciduous, grows so poorly that it cannot be utilised for at least three months. It long survives the hot season and dominates the others in October and November, but, in January and February, it completely ceases growth, only recommencing when white ramie begins again (March-April), almost regaining the lost time. At the end of the season green ramie wins and only begins to weaken in November, while white ramie begins in July.

Green ramie visibly suffers during the winter, whilst the white, though stopping growth in winter, retains its initial vigour; but the growth of the latter stops as soon as the heat becomes intense and continuous. Moreover it suffers visibly from sudden heat waves. These observations were made during the 2nd and 3rd year and the author adds those made in the 4th and 5th (last) of the plantation: — green ramie gradually fades from year to year, as does the white though less clearly if still visibly owing to the effect of the great heat.

**INFLUENCE OF THE SOIL.** — This is considerable. Valleys of secondary watercourses could probably be found with the rich and permeable soils that suit ramie; very few such soils are free from the danger of floods and cold.

**GROWTH AND SPACING.** — Growth was rapid, but limited, quickly stopped. The stems attained their full length in 6 or 7 weeks, afterwards making little progress. No stems were obtained more than 63 in. long, save in the La-Pho garden and in a specially treated field, where some as long as 86 in. were obtained. The plants were 20 in. apart in the rows and 28 in. apart between the rows, an insufficient density.

**Hoeing and Weeding.** — Ramie must always be kept very clean, which is expensive. Summer weedings should be no less than 4 and to keep it as clean as is really necessary, the number should be 8. The author reckons that the upkeep alone of the plantation costs 20 *piastres* per *muu*.

PERCENTAGE OF FIBRE. — From 44 lb. of green material weighed the day when cut (after 24 hours the weight has already decreased by 10 %), percentages of fibre were obtained varying from 2.78 to 3.38. Each year, the first cut, gives a higher percentage.

YIELD AND COST PRICE. — The author has estimated a yield of 1220 lb. of 'hemp' per hectare for 3 cuts in the year, or 475 lb. per *mau*. Considering that it might be sold at 600 francs per metric ton or 129.60 fr. per *mau*, i. e., 52 *piastres*, the expenses (hoeing and weeding, cutting, defibration, drying of fibre, baling, depreciation in 10 years of plantation) come to 50 *piastres*.

RAMIE IN INDO-CHINA (CONCLUSIONS). — As has been said, 4 varieties were under consideration : — white ramie, green ramie and the two yellow and red varieties ; of these the first two seem of most interest. Although the observations made are insufficient to allow a final classing, they justify the apprehensions felt by the author during the trials regarding this crop about which all has to be yet learnt. It appears that green ramie (*Boehmeria utilis*) would not give the regular and abundant crops reported from other warm countries. Green ramie is persistent and seems to be the variety most suited to very hot climates with no winter. It suffers in Bengal, where it falls short of its reputation, as the author found with Mr. PRAIN, at the Calcutta Botanical Garden, and with Anglo-Indian planters. White ramie, on the contrary, seems to be the variety for temperate climates. It does well in France in Vaucluse, Limoges, even at Gennevilliers, as is known, but it does not resist the trying summers in Tonkin.

Yellow and red ramie are acclimatised in Tonkin. Yet they grow less vigorously than the white ; they run no risk there, but their stems are less fine.

It is only a question of appearances, noted not only at La-Pho, but also on private estates. Several years of observations are required in order to find by what modifications of the classical cultural methods the yield of those rames already acclimatised may be improved or the influence of the climate attenuated for the exotic, white and green rames. But there is another question, apart from the purely cultural stand point, that relates to the production of ramie — to find a rational cultural method so as to obtain, with the minimum expense, good quality ramie fibre, utilisable commercially, in paying quantities, from plantations of sufficient duration.

The chief of the La-Pho station was aware that the really rational cultural conditions for ramie were unknown. All remains to be learnt and discovered, for no plantation in the world has been continued successfully, giving lessons, examples, or, if it exists, it has not been revealed in such a way that it can be considered as a living enterprise for cropping ramie fibre. The amateurs, for conceit, inventors and business men for self-interest, have not always made known what they have learned or have often asserted that of which they were ignorant, when they have not deceived the public.

The observations made at La-Pho in 10 fields, i. e., on 10 different sites, over an area of 2 *maus* have shown that the choice of sites suitable

for ramie is very limited, so much so that it may be foreseen that large areas will not be occupied by this crop as yet in Tonkin. In fact, clay soils, with abundant moisture, are unsuitable for ramie, as are highlands whether they are hard, stony or sandy. Ramie can be grown neither on slopes, nor on narrow terraces that dry up in a few days, or on impermeable terraces.

Alluvial, rich, deep soils, theoretically so suitable, are, for several months of the year (those when growth is at its maximum and when the ramie should produce), soaked like a sponge. A plantation can only be started if water can be removed or given, by drainage and irrigation, at the required time. It is, therefore, if one wishes to grow it on a large scale, a crop for an engineer and a clever, resourceful engineer. Besides, all these soils are threatened by the great floods, which are fatal to ramie.

So much for the large-scale cultivation of ramie and it is worth while to add that ramie can be grown almost everywhere, round the house in tiny plots of soil, raised near the houses, cultivated like gardens, with soil brought to the spot, as it is grown on high land by the mountain dwellers who might produce much more were they guided and encouraged by better prices.

The studies and practical tests made by the author have resulted in these observations, which state the problem much more clearly than before. The result is not very encouraging and only enables the author to indicate the difficulties to be overcome, the illusions to be avoided and a programme of researches to be carried out.

Ramie has been discussed too much in scientific literature and business circles for the Indo-Chinese administration not to have attempted to ascertain whether, as has been asserted with confidence, Tonkin is suited to the crop.

1359 - **Agave Cultivation in Tropical and Intertropical Countries Especially Madagascar.** — HOFFMANN, A., in the *Revue Agricole et Vétérinaire de Madagascar et Dépendances*, Year III, No. 19, pp. 219-226. Tananarive, 1918.

Of late years agave cultivation has continuously extended in nearly all tropical and intertropical countries. In order to encourage the growth of this crop in Madagascar the author publishes the following general information as to this textile plant and its production.

The agave is indigenous to Mexico, South America and the southern part of North America. The first plants were imported into Europe and India about the middle of the sixteenth century but Europeans only began to take an interest in this crop towards the end of the nineteenth century. The following species are known : —

*Agave americana*, the maguey of Mexico, growing wild in temperate zones, with a very fine, white fibre ; its sap is used in treating skin diseases. *A. decipiens*, or false sisal, of no cultural interest. *A. mexicana*, imported into Madagascar, where its growth is not advisable on account of the strong, lateral spines. *A. vivipara*, one of the few varieties suitable, for damp soils, mostly grown in India. *A. Lespinassei* or "Zapupe" (VINCENT), one of the best varieties for yield and hardiness. *A. rigida* var. *elongata*, indigenous

to Mexico, prefers a warm, dry climate and very dry, stony, calcareous soils; rarely grows above an altitude of 1000 ft. One sisal plant yields 16 to 40 leaves a year; the fibre content varies from 3.5 to 4.2 %, according to the soil; besides extracting the fibre, attempts have been made to extract alcohol from the pulp (residue of the decorticated leaves).

Although very hardy, agaves have certain requirements: light volcanic soils, dry and rich in lime suit them best; too damp or clayey soils should be avoided. Shade and torrential rains are very harmful. In short, they require a tropical climate, well drained soils and a distinctly dry season.

As regards the nursery and the preparation of the soil the author gives the following advice: —

If the soil is not rich enough, some manure mixed with wood ashes should be turned under. The earth should be banked up well round each plant and the soil must be kept free from weeds; when, after 12 or 16 months, the plants are 14 to 16 in. high, they can be transplanted. The methods of preparing the soil and planting obviously vary according to the district; the soil should be well cleaned and tilled, and if too poor in lime, it should be limed. The distance between the plants varies according to the districts and is controlled by the desire to plant as many plants as possible per hectare; the author advises  $78 \times 98$  in. or  $78 \times 118$  in. which gives 1650 or 2000 plants per hectare; After transplanting, before or towards the end of the rainy season the attention required consists in replacing dead plants, cleaning or weeding, removing the suckers that live at the expense of the parent plant (these suckers, dried in the sun serve, with the bulbils, for reproduction).

The harvest takes place 3 years after transplanting. Mature leaves can be recognised by their yellowish-green colour and the silver-grey colour of the terminal spine; at the first cut each plant can give 25 to 35 leaves.

The author next gives details regarding transport to the works and the works itself that may be required near a plantation. He gives a scheme for a plantation, with running expenses for Madagascar, and arrives at a total of 200 000 francs (including the works and not counting administrative expenses) for a 200 hectare plantation in Madagascar. Under these conditions the cost price per hectare ready to be exploited comes up to about 1000 francs. If the yield is calculated, it will be seen that the products of the first two years will pay all the cost of plantation. In countries where labour is still relatively cheap and the value of land moderate (as in Madagascar) a profit of 500 to 600 francs per hectare per year may be counted on.

In conclusion the author remarks that the agave is one of the few plants that suffer little from insects and fungi; even locusts rarely attack it.

important. The plants that produce these essential oils in the Dutch East Indies are wild or cultivated.

Among the wild species may be mentioned the "cajuput" (1) from which is obtained cajaput oil by distilling the leaves. Adulteration with paraffin, benzine, etc., is all the more common as it is not easily detected; adulteration may, however, be detected by violently shaking a bottle half-filled with the oil; the air bubbles produced vanish at once in the pure liquid, remaining, however, for some time in the adulterated product. The green colour of the oil is due to the presence of copper and chlorophyll compounds; this is why a small piece of copper is often added to the product. Cajaput oil is much used in therapeutics. It is mostly exported to Singapore, the chief market of the product for British India. It is also sent to the United States where it is used in making a number of proprietary pharmaceutical products. Good quantities are also bought by Siam, Hong-Kong and Timor Island; in Europe, the chief buyers are Great Britain, Holland and Germany. In 1913, 1914 and 1915 the total exports were 124 228, 65 469 and 79 863 kg. At present there is a tendency for eucalyptus oil to replace this product.

The species cultivated occupy an area of about 3 000 hectares, 2 700 of which are in Java alone. They are often found with other crops on large estates. The chief essential oils furnished by these species are given below:—

*Citronella oil* is obtained by distilling "serchwangi-grass" (1) a grass mostly cultivated by the natives; 1 000 kg. of the grass yield about 7 kg. of the oil, which is mostly used in soap and perfume making (synthetic essence of roses). The chief producing countries are Ceylon and Java; Java produces by far the smaller quantity, but the product is of better quality and fetches twice the price of the other. The exportation of Javanese citronella oil to all countries was:—1913, 75 230 kg.; 1914, 136 654 kg.; 1915, 233 326 kg.; 1916, 428 743 kg.; 1917, 515 763 kg. The largest importers are the United Kingdom, the United States and Japan.

*Lemon-grass oil*.—Produced from the grass of the same name (1), the yield being 0.2 %. At present importers prefer the oil from Cochin-China and Reunion.

*Cananga oil*.—Obtained by distilling the fresh flowers of the cananga (1), a tree that usually flowers twice a year, giving 60 kg. of flowers; to obtain 1 kg. of oil requires at least 350 kg. of flowers. This product is only exported in small quantities and it is not specially mentioned in official statistics; it has to compete with ylang-ylang oil from the Philippines, which costs 10 times as much (2).

(1) The cajuput is *Melaleuca leucodendron* L. "Serchwangigrass", giving citronella oil, is *Andropogon Nardus*. Lemon grass is *A. Nardus* var. *flexuosus* Haek. Cananga is *Cananga odorata* (see Note 2). The two Magnolias giving champaca oil are *Michelia Champaca* L. and *M. longifolia*. Vitivert or cuscus grass is *Andropogon muricatus* Rets. (Ed.).

(2) Ylang-ylang oil consists of the first fractions obtained in distilling the flowers of *Cananga odorata*; cananga oil is the whole product from distilling these flowers. (Ed.).

*Champaca* oil is obtained by distilling the flowers of two *Magnolia*-ceae (1) common in India and which flower throughout the year; the oil-yield of the flowers is about 0.2 %.

*Vetiver* oil is obtained from the roots of the vetiver or cuscus grass (1); the roots contain from 0.4 to 0.9% of essential oil; no official statistics as to its exportation are available.

*Patchouly* oil is obtained by distilling the stems and leaves of *Pogostemon Patchouly* Pell. The leaves can be gathered repeatedly, at intervals of 6 months. The east coast of Sumatra furnishes most of the supply; so far it is not specially mentioned in the official statistics.

*Geranium* oil is obtained by distilling the leaves of *Pelargonium* spp., the essential oil of which much resembles that of the rose. It is widely cultivated, especially in rubber plantations. During some researches it was found that 71 plants gave 76.5 kg. of leaves, which produces 53 cc. of essential oil containing as much as 58.8 % of geraniol.

1361 — *The Cultivation of Pyrethrum in Switzerland.* — FAES, H., in the *Schweizerische Apotheker-Zeitung*, Vol. XVI, p. 429, 1918, reproduced by HARLAY in the *Journal de Pharmacie et de Chimie*, Series 7, Vol. XVIII, No. 7, pp. 213-215. Paris, 1918.

The pyrethrum from whose flowers the insect powder is obtained is the *Pyrethrum cinerariaefolium* of Montenegro, Dalmatia, Herzegovina and Istria, which grows up to an altitude of 3250 ft., and *P. roseum* and *P. carneum* of the Caucasus and Northern Persia, which grow up to 6500 ft. Since 1912 the author has grown *P. cinerariaefolium* in Switzerland and it has quickly spread. At the end of 1917, 97 plantations were established, with a total of 24890 plants. The dried flowers are now worth 11d. per lb. and the seeds 36s. 8d.

Sowing is done in April to May or in July to August with freshly-gathered seeds, in lines 8 in. apart; a mulch of leaves or fresh manure should be given, followed by watering and tilling. After 2 or 3 weeks the plants are already vigorous and they must be transplanted into warm, gravelly soil at a distance of 20 × 24 in.

The plantation begins to yield well after the second year. Flowering takes place in May. The flowers are all gathered in June, when most of them begin to open, and they are spread out in a shed in the shade to dry. The yield of dried flowers is 28 to 29 % of the fresh flowers. Flowers to be used for seed-production for extending the plantations are left on the plant until they have completely expanded (about July 15).

Experiments have shown that Swiss pyrethrum powder is quite comparable, as regards quality, to that from Dalmatia and Montenegro.

1362 — *The Production and Price of Orchil.* — *In-en Utvoer*, Year III, No. 40, p. 897. Amsterdam, 1918.

Orchil, a dye extracted from various lichens (2), is used for imparting olive-green and brown shades to feathers, etc., especially ostrich feathers.

(1) See note on previous page.

(2) These lichens belong to the genus *Roccella* (*R. tinctoria* D. C.; *R. phycopsis* Ach; *R. fuciformis* D. C.), There are a number of substitutes for orchil, especially synthetic azo-compounds. (Ed.)

It is extracted chiefly in the United Kingdom, the lichens being imported from the Cape Verde islands. Of late years the United Kingdom has exported the following amounts to the United States. — 1914, 229 068 lb.; 1915, 372 803 lb.; 1916, 512 607 lb.; 1917, 209 383 lb. The increased exportation of orchil up to 1916 is due to the decrease in that of the German dyes; the increased in price to 6 ½ d. per lb. in 1917 against 3.7d. in 1914 is equally significant.

1363 — **The Production of Divi-divi in The Dominican Republic.** — MC LEAN, A., in *Commerce Reports*, No. 120, p. 708, Washington D. C., 1918.

Divi-divi is the commercial name for the astringent pods of *Caesalpinia coriaria* Willd. a leguminous shrub indigenous to the Dominican Republic. The plant is between 20 and 30 ft. high and bears white flowers; the fruit is a bean, about 2 in length, 1 in. in width, and about ¼ inch in thickness; it contains about 30 % of a tannic acid used in the manufacture of leather. The bean ripens and falls to the ground from November to April; if it rains while the beans are on the ground they are ruined and large quantities are lost in this manner, as November and December are rainy months in this Republic.

Whole families of the poorer people devote their entire time to gathering divi-divi beans and bringing them to market. It is difficult to state the average yield per shrub; some produce as many as 70 lb. or more, and others of the same age yield only half that quantity. Almost all of the divi-divi shrubs in the Puerto Plata consular district are to be found in the arid lands on the Province of Monte Cristi. They are not cultivated, but grow wild over vast sections of the Province. The town of Monte Cristi, on the north coast near the Haitian border, is the centre of the industry and is the port from which most of it is exported. Divi-divi is usually packed for export in jute sacks weighing from 110 to 125 lb. gross. It was formerly shipped to some extent in bulk in sailing vessels, but this mode of shipment has been discontinued, as it was not found practicable. The value of this product is determined by its quality and appearance; large, plump and ruddy beans are in good demand, while small black and broken beans are unsalable.

The annual exports of divi-divi from Monte Cristi formerly exceeded 2 000 000 lb. but of late years they have fallen below these figures. This decline in the output is attributed to a species of orchid, which lives on the shrubs. This parasite reduces the production and often kills the plant. Nothing has been done to eliminate this pest, although it has spread at an alarming rate, so that there is hardly a shrub which is not infested with it.

Prior to the war divi-divi was exported to Hamburg almost exclusively. The past few years, however, it has found a ready market in New York. The prices were formerly fixed in Hamburg at from 9 to 12 marks per 50 kilos (from \$ 0.0195 to \$ 0.026 per lb.), but now it brings from \$ 50 to \$ 55 a ton of 2 000 lb. f. o. b. New York.

RUBBER,  
GUM AND RESIN  
CROPS

- 1364 - Comparative Results of the Growth of *Hevea*, *Castilloa* and *Funtumia* Rubber Trees at Tobago. — VERTEUIL, J. de (Superintendent of Field Experiments), in the *Bulletin of the Department of Agriculture, Trinidad and Tobago*, Vol. XVII, Pt. 1, pp. 50-51 + 1 Table. Trinidad, 1918.

In 1907 five experiment plots were planted with alternate rows of *Hevea*, *Castilloa* and *Funtumia*. When the trees were four years old (in 1911) the different plots were subjected to the following treatments: — 1) manure; 2) ammonium sulphate and potassium sulphate fertiliser; 3) indigo as cover crop; 4) mulched with grass; 5) control.

As a result of the shade from the rubber trees it was impossible to grow the cover crop in 1914, and in 1915, manuring and mulching were no longer carried out regularly. The circumference of the trees was measured in 1911, before the plots were treated, and then regularly each year till December 1916. The results obtained for each species respectively in each plot are given in a table and lead to the following conclusions: —

The *Castilloa* grew most rapidly and the *Funtumia* most slowly. After manuring the annual growth of *Hevea* was superior to that of *Castilloa* and best in the plot with a cover crop. The *Castilloa* did best in the plot fertilised with ammonium sulphate and potassium sulphate, and the *Funtumia* in the control plot.

In short, *Funtumia* derived no benefit from the treatment of the plots, *Castilloa* no apparent benefit and *Hevea* a slight benefit. It should be noted that the soil of the various plots, of excellent quality, was far from exhausted by crops at the time the experiments were undertaken.

## FORESTRY

- 1365 - Effect of Grazing upon Western Yellow-Pine Reproduction in the National Forests of Arizona and New Mexico, U. S. A. — HILL, R. R. (Grazing Examiner), in U. S. Dept. of Agriculture, Bulletin No. 580, *Contribution from The Forest Service, Professional Paper*, pp. 27 + 2 Figs. + 3 Plates. Washington, D. C., 1917.

The present bulletin gives the results of a study undertaken to determine the character and extent of the damage to young growth of western yellow pine in the southwestern United States due to the grazing of live stock, and to find out the best means of keeping such damage at a minimum while permitting proper utilisation of the range.

Of 8 945 trees of a size subject to grazing, observed over a 3-year period, 1 493 or 16.7 %, were severely damaged each year and 1 442, or 16.1 % were moderately damaged. The most injured are the seedlings, 21 % of which are seriously damaged. The damage gradually decreases with an increase in the size of the trees. Trees above 4.5 feet in height are free from severe injuries from browsing, but those between 3 and 6 feet in height are likely to be rubbed severely.

The greatest amount of damage occurs during the latter half of June and the first part of July, or when the effects of the spring dry period are most pronounced. The least damage occurs during the first few weeks of the growing period, or before June 15. A very considerable amount of damage is done during the main growing season and during the autumn drying period.

Under normal conditions of grazing, cattle and horses, and inci-

dentally burros, do an inconsiderable amount of damage to reproduction. Sheep under the same conditions may be responsible for severe injury to 11 % of the total stand. On overgrazed areas all classes of stock are apt, however, to damage small trees severely. Cattle and horses may damage about 10 % of all reproduction. When sheep are grazed along with them, however, at least 35 % of the total stand may be severely damaged. Ordinarily sheep cause about seven and a half times as much damage as cattle.

The density of forage does not affect the amount of damage that may be caused on a given area. The suitability of the forage to the class of stock using a range has also an important influence upon the amount of damage to timber reproduction. Because of the suitability of the pure bunchgrass type to sheep grazing, the reproduction over approximately  $\frac{1}{3}$  of the bunchgrass type on one National Forest is being seriously injured. The amount of palatable feed available during the grazing season, and especially during June and July, has also an important bearing upon the amount of damage that grazing will cause to reproduction. During a favourable year the damage may be 18 % less than during a subnormal year.

The manner in which stock is handled has much to do with the severity of grazing damage. Cattle are likely to injure 22 % of the trees between 3 and 6 feet in height that grow on areas where they are accustomed to congregate. Sheep severely injure reproduction along driveways and on bed grounds.

Grazing is believed to have a largely neutral effect upon the germination and early establishment of reproduction, but to have an important effect in reducing the destruction of reproduction by fire. The effect of grazing upon the height growth of reproduction is marked. Severely injured trees grow only from  $\frac{1}{2}$  to  $\frac{1}{3}$  as fast as uninjured trees. Grazing injuries are not responsible for the common deformities of mature trees.

It appears that the permanent effects of grazing injuries upon the development of damaged trees are not serious, provided they have a chance to recuperate. If grazing is unrestricted, about 15 % of the total stand is likely to be killed during the period required for reproduction to become established. Reproduction that has been impoverished greatly by grazing is more likely to be attacked by fungi and insects than uninjured and vigorous reproduction. However, the ordinary grazing injuries are not believed to increase seriously the danger of such attacks.

**1366 - National Parks in Spain.**—*Boletín de la Real Sociedad Geográfica, Revista de Geografía colonial y mercantil*, Vol. XV, Nos. 8-10, pp. 376-377. Madrid, August-October, 1918.

By the royal decree dated August 16, 1918, was founded in Spain, besides the National Park of "la Montaña de Covadonga" or "Peña Santa" in the Asturian-leonais Picos de Europa (1), the National Park of "Valle de Ordesa" or "río Ara", in the Arragonese Pyrenees.

## LIVE STOCK AND BREEDING.

## HYGIENE

1367 - On Ocular and Locomotor Troubles in Equine Trypanosomiasis, in Morocco. — VÉLU, H. (Research Laboratory of the "Service de l'Élevage"), in the *Bulletin de la Société de Pathologie Exotique*, Vol. XI, No. 7, pp. 506-568. Paris, 1918.

The author considers ocular and locomotor troubles and their respective importance in equine trypanosomiasis, in Morocco (1).

*Ocular troubles* (yellowish conjunctiva, sometimes congestion of the conjunctiva, oedematous eyelids, often true conjunctivitis as well) are fairly constant, but they are not important as locomotor troubles. Nevertheless, ocular troubles can become much more serious in grave cases of rapid course: the eyelids are swollen, the eyes completely closed, there are tears of blood, and even keratitis is sometimes observed. The author quotes one of these serious cases which he had examined closely.

*Locomotor troubles* are, together with stupefaction, among the most constant symptoms, although they vary according to the animal and the intensity of the attack. They may be shown by slight difficulty in walking, unsteady trotting, as well as by being more evident, even showing paraplegia and an incomplete coordination of movement which may lead to loss of balance. Very evident locomotor troubles are, in addition, accompanied by incontinence of urine.

1368 - On the Mortality from Trypanosomiasis of Dromedaries. — SERGENT, EDMOND and ÉTIENNE, FOLY, H. and LHERITIER, A. (Institut Pasteur d'Algérie), in the *Bulletin de la Société de Pathologie Exotique*, Vol. XI, No. 7, pp. 568-570. Paris, 1918.

The observations described by the authors are those on the first cases of trypanosomiasis of the dromedary ("debab") which could be controlled by laboratory methods during the whole of their duration. In 2 cases of natural infection the animals died after 4 months; in one case of infection by inoculation the animal seemed to have recovered in 18 months. The authors have also considered the part played by over-driving and by intercurrent diseases in the death of infected dromedaries and they have found that trypanosomiasis of the dromedary decreases its resistance to fatigue and privations (action of cold, fasting, heavy rain, etc.) and renders it much more sensible to other infections, which is a character very similar to malaria.

The authors state that amongst Algerian livestock, 10 % of the animals are usually infected with trypanosomiasis.

1369 - Endoglobular Parasites of the Horse in Morocco. — VÉLU, H., in the *Bulletin de la Société de Pathologie Exotique*, Vol. XI, No. 1, pp. 26-27. Paris, January 9, 1918.

Work carried out in the research laboratory of the "Service de l'Élevage" in Morocco.

\*In Morocco there are two equine piroplasmoses:—

1) true piroplasmosis, due to *Piroplasma caballi*, with haemoglobinuria, paresis, and sometimes paraplegia; 2) equine nuttalliosis due to *Nut-*

(1) See also R., June 1917, No. 562. (Ed.)

*tallia equi*, of which the author has seen but one case, which ended fatally. In this case there was very strong jaundice and haemoglobinuria; three-fourths of the erythrocytes were parasitised at the moment of death and more than half of them contained two or more parasites.

1370 — **The Etiological Cause and Treatment of Granular Dermatitis of the Horse.** — VAN SAGEGHEM, R., in the *Bulletin de la Société de Pathologie Exotique*, Vol. XI, No. 7, pp. 575-578. Paris, 1918.

Some recent experiments of the author confirm his own previous observation that flies transmit the larvae of *Habronema*, the etiological cause of "summer sores". The author has further observed that the parasite found in the nodules of "summer sores" is a wandering larva of *Habronema muscae*. Larvae of *Musca domestica*, bred in the laboratory were placed in fresh manure from a horse known to be parasitised by *Habronema muscae*. The flies bred out from these larvae were found to be infested by *Habronema* larvae at the rate of 70 %; the fly can only be infected during its larval stage. Observations on the *Habronema* larvae isolated from the flies enable the author to state that when placed on the dry skin or on the hair the larvae could neither move about nor pierce the skin, and so died quickly, and that they could only fix themselves at breaks in the continuity of the skin or on lubricated mucosa. Direct infestation by manure is thus very uncertain. The treatment may be prophylactic and curative.

**PROPHYLACTIC TREATMENT.** — This consists in fighting against *Habronema*, which lives in enormous numbers in the stomach of the horse. To destroy the adult form, administer arsenic at the rate of 1 to 2 gm. per day; to destroy the larval form, abolish the permanent litter and bury the fresh manure each day in the fermenting manure heap; the *Habronema* larvae, like those of flies, are killed by the heat developed in the manure; this is the biothermic method proposed by ROUBAUD (*Comptes Rendus Acad. des Sciences*, 1915, p. 325). It is obvious that combating the flies helps in fighting against the spread of summer sores, which must be specially protected in the hot weather by dusting the sores with some drying powder.

**CURATIVE TREATMENT.** — The author has obtained the best results by disinfecting the sore, then applying a power composed of 100 parts of gypsum, 20 of alum, 10 of naphthaline, and 10 of quinine. The sores soon heal up if the plaster is kept renewed as long as there is any break in the skin.

In an additional note M. ROUBAUD says that the *biothermic method* suggested by him ought to be more widely used in veterinary hygiene, for the heat produced by fermenting horse manure can also be used for destroying the eggs and larvae of other parasites of the horse — oxyurus, ascarids, strongylids, etc. — present in the manure.

1371 — **The First Tests of Vaccination against Epizootic Lymphangitis.** — BOQUET, A., NÈGRE, L., and ROIG, G., in the *Bulletin de la Société de Pathologie Exotique*, Vol. XI, No. 7, pp. 551-553. Paris, 1918.

By means of cultures of RIVOLTA's parasite, obtained recently, the authors have been able to carry out tests of preventive vaccination against epizootic lymphangitis (1), which previously was impossible as the crypto-

(1) See R, Sept. 1918, No. 1003. (Ed.)

coccus had not been cultivated in series. The method is based on the fact, discovered by the authors, that the serum of animals affected for more than 15 days, or cured, is rich in antibodies and that the natural or experimental disease confers immunity. The colonies of cryptococci, two months old, are ground in a dry state, emulsified in physiological salt solution, then placed in capsules which are heated at 62-64° C. for one hour. Four hypodermic injections of 5 cc. are given in the neck at intervals of 8 days.

The authors describe, as an example, an experiment made on 4 healthy horses treated by this method. The injections caused a slight oedema at the point of injection, followed, after its disappearance, by a slight hardening, but causing no open abscess. Eight days after the last injection, 2 horses were given, as a test, a hypodermic injection of 4 cc. of living cultures of cryptococci emulsified in physiological salt solution. The results were as follows:—the two vaccinated horses not inoculated with living cultures showed no symptom whatever of lymphangitis after 3 months; nor did the other 2 horses. The authors conclude that the vaccinated horses seem to have been immunised by the injection of heated cultures against the inoculation of living cultures of RIVOLTA's cryptococcus. They further add that the 4 horses vaccinated lived in the closest contact with gravely infected animals, and that these results show the possibility of vaccinating horses against epizootic lymphangitis by inoculation of sterilised cultures.

1372 — **Distomatosis and Glycosuria in Cattle, in Brazil.** — PARREVIA HORTA, P., in *A Lavoura*, Year XXII, Nos. 3 and 4, pp. 157-158. Rio de Janeiro, 1918.

In the course of his work on rabies the author found, some years ago, while doing post mortem examinations on cattle, the presence of a helminthid often completely blocking the bile ducts and which was a large distomum now known as *Eurithrema pancreaticum*. Since then, when carrying out post mortems the author has always looked for this distomum and he states that there are few occasions when he has not found the parasite. Recently he also observed it in large numbers in the pancreas of a calf, thus showing that it can abundantly infest a young animal.

Seeing that these parasites are found in large quantities in the liver of animals suffering from glycosuria, the author suggests a relation of cause and effect between the two facts and throws doubt on the value of glycosuria as a diagnostic index of rabies, an index usually considered as quite sure.

1373 — **The Presence of the Virus of Rabies in the Spleen.** — REMLINGER, P., in the *Annales de l'Institut Pasteur*, Vol. XXXII, No. 8, pp. 406-412 + 4 Tables. Paris, 1918.

In a series of inoculations of the spleen of a guinea-pig that had died from rabies into other guinea-pigs, the author found that the virus of rabies occurs much more often in the spleen than is generally admitted. The presence of the virus in that organ is completely independant from any post-mortem generalisation (1), as putrefaction is rather a hindrance to the diffusion of the virus of rabies in the spleen.

(1) See R. Oct., 1918, No. 1127. (Ed.)

1374 — **The Control of the Blow-Fly and the Sheep Maggot Fly in Queensland** (1). — *Queensland Agricultural Journal*, Vol. IX, No. 4, pp. 136-137. Brisbane, April, 1918.

I. — **BLOW-FLY TRAP.** — Mr. H. A. Adams, of Vallerói, Queensland, has made a cheap trap for blow flies (*Calliphora* sp.) with a petrol tin. The tin is cut near the square upper end, on three of the vertical sides, then the upper part thus cut is bent over on the vertical side left intact; in this way an upper and a lower compartment are formed. In the lower half decomposed sheeps' entrails are put as a bait and in the upper half a sweetened arsenical solution. Two strips of flannel, about 2 in wide are arranged so that they reach the bottom of the liquid and rest on the bait which is thus kept well poisoned. The bait must be well decomposed before using or the arsenic will prevent it from decomposing.

II. — **CONTROL OF THE SHEEP MAGGOT FLY** (*Lucilia sericata*). — The author (L. G. JONES) thinks that the dags where the fly usually lays her eggs, should be left on the sheep, instead of cutting them as is often done; the dags should be poisoned by submerging them in a very strong arsenical solution. The solution is prepared by heating  $\frac{1}{2}$  lb. of washing soda in 4 gallons of rain water nearly to boiling point and then adding 1 lb. of commercial arsenic; it is then brought quickly to the boil, continuing for 15 minutes. As soon as the mixture is lifted off the fire, 4 pints of cold water are added and stirred well in, as after arsenic has been boiled in water it goes more completely into solution when suddenly put off the boil. The author is of the opinion that there is no advantage in using poisoned offal baits. It has even a contrary effect for, after a short time the fly leaves its natural medium — carcasses — and attacks the sheep. On the other hand the poisoned dags repel the flies, to the advantage of the sheep. In addition the sheep should have an arsenical sheep lick (4 parts of salt + 1 part of a mixture of  $\frac{3}{4}$  of iron ore and  $\frac{1}{4}$  of mispickel). All the arsenic would not be absorbed by the organism, and a part would pass out with the droppings, which would then be in such a condition as to retard greatly the development of the maggots. If the fly lays eggs on any part of the sheep's body other than the tail, it is because the yolk is diseased (damp, sticky and often badly smelling), the sheep being in bad health. In this case iron is a very appropriate medicine for sheep (2).

1375 — **On a New Disease of the Dog in Senegal.** — HECKENROTH, F., in the *Annales de l'Institut Pasteur*, Vol. XXXII, No. 8, pp. 399-403. Paris, August, 1918.

The author records the appearance in Senegal of a special, and possibly new, disease of the dog. It is chiefly shown by nervous disorder ending

(1) See R., 1914, No. 1017; R., 1915, Nos. 401 and 1051; R., 1916, No. 1295. (Ed.)

(2) Reduce to a fine powder and mix 1 part of ironstone (containing chiefly a mixture of ferrous and ferric oxides) with 4 parts of mispickel; mix the whole with salt at the rate of 1 to 4 and give the stock free access to it in their troughs. This provides a good remedy against intestinal and blood parasites as well as an excellent tonic. The author made this discovery by noting that, in certain pastures of New South Wales the sheep themselves seek for the tickholes where the ironstone occurs. Pastures where ironstone occurs are among the most paying (L. G. JONES, a Natural Remedy for Worms and Blood Diseases in Stock, in the *Queensland Agricultural Journal*, Vol. IX, No. 2, pp. 48-51. Brisbane, February, 1918.

in death and, in some points, resembles rabies, of which the author suggests it may be an atypical case.

The symptoms observed and the results of the laboratory researches, directed especially towards the diagnosis of rabies, are described. NEGRI corpuscles in the horns of Ammon were sought for in four dogs but with negative results.

1376 - Description of a Bacterium which Oxidises Arsenites and of Another which Reduces Arsenates, Isolated from a Cattle-Dipping Tank in South Africa. — GREEN, H., in *The South African Journal of Science*, Vol. XIV, No. 11, pp. 465-467. The Cape, June, 1908

A number of arsenic-resistant organisms have been isolated from a cattle-dipping tank. These include: —

1) *An oxidising organism*, changing arsenites to arsenates, causing deterioration of arsenical dips, and which seems to be the only one to which rapid oxidation of arsenites is to be ascribed. It has been provisionally named *Bacterium arsenoxydans*; its dimensions are variable (length 1 to 3  $\mu$ ; breadth 0.3 to 0.6  $\mu$ ). It is easily differentiated from other organisms by its high tolerance to arsenite, the limit of tolerance being about 1 %. Under suitable conditions the rate of oxidation increases as the concentration of arsenite decreases.

2) *A reducing organism* which under normal conditions rapidly reduces arsenates to arsenites. This organism has been named *Bacterium arsenreducens* and appears to belong to the colon-typhoid family, from the other members of which it can easily be differentiated by its high resistance to arsenites. It is polymorphic, motile and of very variable dimensions (length 1 to 6  $\mu$ ; breadth 0.3 to 0.6  $\mu$ ).

Other arsenic-resistant organisms have been isolated from the dipping tank. They neither reduce arsenate nor oxidise arsenite. Amongst these are members of the *putridum* group one of which, *B. fluorescens non-liquefaciens*, can grow freely in concentrations up to 1 %  $\text{As}_2\text{O}_3$  as arsenite.

1377 - Elimination of Arsenic after Ingestion by, and Injection into, Live Stock, and After Absorption through the Skin by Dipping. — GREEN, H. II., in *The South African Journal of Science*, Vol. XIV, No. 11, pp. 472-473, The Cape, June, 1908.

Numerous experiments have been carried out to show the distribution of arsenic in the stomach and intestinal tract at various intervals after dosing and on its rate of elimination in the urine and faeces. The distribution of arsenic in the different compartments of the stomach of the sheep depends upon the path taken in swallowing. If the animal takes material voluntarily, as in the form of a lick, the greater proportion passes into the rumen, and thence slowly through the abomasum into the intestine. If the animal is forcibly dosed, a considerable part of the arsenic may pass direct to the abomasum, from which it is more rapidly passed on into the intestine.

Rate of absorption and elimination of soluble arsenic is rapid, and the path of elimination of either arsenite or arsenate of sodium is chiefly by the kidneys, about  $\frac{4}{5}$  of the dose appearing in the urine, and only  $\frac{1}{5}$ , or less, in the faeces. After ingestion 25 % of the dose may be eliminated in the

urine within 24 hours, and as much as 60 % within 48 hours; later, the urine only contains traces. In the faeces the maximum output usually occurs in the third day, and by the seventh or eighth day the solid excreta are practically arsenic-free.

When soluble arsenite is injected straight into the blood stream the path of elimination is almost wholly through the urine. Elimination begins almost at once, and several per cent of the injected amount may appear within half an hour.

The data for horses and cattle are more limited. With the horse, however, the absorption of soluble arsenic appears to be less complete, and a large proportion is eliminated in the faeces. The amount of arsenic eliminated by cattle and horses after dipping in arsenical tanks is very small, and the currently accepted data are shown to be erroneous. Currently accepted data for arsenic retained in the skin of dipped animals are also shown to be too high.

**1378 - Researches on the Utilisation of Inosite by the Animal Organism.** — I. ANDERSON, R. J., Influence of Inosite on the Respiratory Quotient in the Dog, in the *New York Agricultural Experiment Station Technical Bulletin*, No 54, pp. 3-9 + 4 Tables — II. ANDERSON, R. J and BOSWORTH, A W, Influence of Inosite on the Metabolism of Man, *Ibid*, pp. 10-16 + 6 Tables. Geneva, N. Y., 1916

FEEDS  
AND  
FEEDING

I. — Inosite, discovered by SCHERER in muscle, has since been found in many animal and plant tissues. The author reviews the chief work done on the utilisation of inosite by the animal organism (KÜLZ, MAYER, STARKENSTEIN), which shows that a very small quantity of the inosite ingested is eliminated by the kidneys. In order to obtain further data on the subject, the author observed the influence of the ingestion of inosite on the respiratory quotient of the dog. The dog was fed with meat once a day together with 2 gm. of inosite per kg. live weight and was then at once placed in a respiration chamber. Under these conditions no noteworthy changes were observed in the respiratory quotient. In addition it was found that inosite is neither stored up nor oxidised, the greater part (about 77 %) being excreted unchanged mostly in the faeces and a small part in the urine.

II. — Results of observations relating to the influence of inosite on the metabolism of man. One of the authors took 10 gm. of inosite 3 times a day. It first acted as a purgative but, after a few days, the stools become normal. Here again, no sensible effect of the ingestion of inosite on the metabolism of man was observed, if it is not a greater excretion of creatinin which became manifest as soon as the subject ceased to take inosite daily. It was also found that, in man, a very small amount (9 %) of the inosite ingested is eliminated in the urine, while the faeces contain none at all. The authors have not yet been able to ascertain how the remaining 91 % is utilised in the organism.

**1379 - The Dietary Qualities of Barley.** — STEENBOCK, H., KENT, H. E. and GROSS, E. G. (Laboratory of Agricultural Chemistry, University of Wisconsin), in *The Journal of Biological Chemistry*, Vol. XXXV, No. 1, pp. 61-74 + 20 Diagrams. Baltimore, July, 1918.

The authors studied the dietary qualities of barley with the help of

investigations similar to those used since the work of HOPKINS, OSBORNE and MENDEL, FUNK, and MCCOLLUM, which have already been applied to various foods (1). Rats were used in the experiments. The food (barley in this case) was first ground to a coarse meal, dried for two hours at 70 to 80°C. and ground to a fine meal to which were added the usual supplements, casein, butter, fat, mineral salts, etc.

CONCLUSIONS. — Barley alone cannot satisfy the requirements of a growing animal, or even allow any noteworthy amount of growth. The addition of the fat-soluble vitamine (given as butter fat) remedies this defect to a certain extent, whereas casein has little effect. The addition of mineral salts gives better results. When all these supplements are added growth is normal. Barley contains the water-soluble vitamine in abundance, but neither sufficient fat-soluble vitamine nor sufficient protein (only 13.6%). Both of these, as well as mineral salts, must, therefore, be added to a ration consisting exclusively of barley, to allow normal growth.

1380 — **The Cleaning and Crushing of Locust Beans and the Removal of their Kernels.**

— GOURN, R., in the *Journal d'Agriculture pratique*, Year LXXXII, No 20, pp 388-389. Paris, October 3, 1918

The author points out that accidents often happen to animals fed on locust beans as a result of the formation of plugs in the digestive tract. For this reason the French Military Administration, when it introduced locust beans into the rations of army horses, ordered that the beans must first be cleaned, crushed and freed from their kernels, only 1 % being allowed to be left in. The food thus prepared was called "caroubine". During 18 months the author was in charge of the supervision and reception of this foodstuff which was sent to all the dépôts of the 15th District. Throughout this period no mishap was reported.

To test the possibility of introducing locust beans into the diet M. FOURCADE, Chemist of the Commissariat Laboratory, made a chemical analysis of them which gave the following results:— moisture 11.79 %; ash, 4.90; fat, 1.90; nitrogen, 23.62; starch, traces. This absence of starch in a seed is notable. There is no doubt that the kernel contains a special substance which causes the formation of plugs and may even have a paralyzing action on the peristaltic movements of the oesophagus. The irregularity of the effects leads to the supposition that this substance occurs in more or less large quantities according to the state of preservation, origin and variety of the locust bean. Grafted trees give pods much richer in saccharose and without the bitter taste of those from seedlings.

The author and M. ANDOUARD have had no opportunity of observing accidents to cattle through eating locust beans. These may be due to digestion by rumination. It is probable that, mastication being less complete (owing to the sharp, woody parts), cases of suffocation are rather more frequent than in horses. The cleaning and crushing of locust beans, and even the removal of the kernels, are advised, the expenses incurred being amply compensated for by the security obtained.

(1) See R. Jan., Feb., March, April, May, June, July, 1918, Nos. 2, 62, 186, 316, 377, 547, 659, 662 and 782. (Ed.)

1381 - Value of Bulbs as a Cattle Food; Investigations in the Netherlands. — EZENDAM, J. A., in *Verslagen van den Landbouwkundige Onderzoekingen der Rykslandbouw-proefstations*, No. XXII, pp. 176-185 + 5 Tables + 13 Figs. The Hague, 1918.

Among the many vegetable products which have been used recently as cattle food there are many which, although their utilisation for such purpose is not new, have rarely been specially examined from the point of view of their food value. This is the case of bulbs, grown over 12 355 acres in the Netherlands in 1913. Under present conditions it was, therefore, natural to attempt to use these bulbs as cattle food, and to study their food value. The Royal Agricultural Station for the Control of Cattle Food at Wageningen made experiments on this subject. The following analytical results were obtained for bulbs of narcissi, tulips, hyacinths, gladioli and crocuses respectively: — Albumen 2.5, 3.8, 2.4, 3.0, 5.2 %; fat, 0.3, 0.2, 0.1, 0.2, 0.3 %; starch 29.6, 34.2, 24.3, 25.4, 42.2 %; crude fibre, 1.8, 1.6, 1.0, 1.4, 2.5 %; moisture, 64.5, 59.2, 71.2, 68.7, 48.9 %; ash, 1.3, 1.0, 1.0, 1.3, 1.1 %. These figures show the bulbs to be comparable to potatoes, the average dry matter content of which is, however, only 25 %, whereas that of the bulbs is much higher, almost double in the case of the crocus. Supposing the digestibility of the starch of these bulbs to be 90 % as in the potato, the starch value on a dry matter basis would be: — narcissus bulbs 27.0, tulip bulbs 31.0, hyacinth bulbs 21.9, gladiolus bulbs 23.8, crocus bulbs 38.8. KELLNER placed the starch value of the potato at 19, so that, according to these data, the maximum price of the bulbs should be 1.42, 1.6, 1.15, 1.25 and 2.0 times that of the potato for the narcissus, tulip, hyacinth, gladiolus and crocus respectively. The food value of these bulbs, therefore, differs widely and is dependent especially on their dry matter content. The scientific literature gives little information on their practical use and most of the investigations on the subject are old. FROHNER (*Lehrbuch der Toxicologie für Tierärzten*, p. 156, 1890) says that *Narcissus pseudo-narcissus* and *N. poeticus* cause poisoning by an alkaloid, narcitine. As such poisoning has been observed in cattle, pigs and goats the unsuitability of narcissus bulbs as a food may be considered definitely established. There is also doubt as to the effects of hyacinth bulbs though when boiled they may be safely fed to stock. The same may be said of tulip bulbs which should be boiled several times renewing the water each time. Crocus bulbs which, according to KOBERT, contain saponin, may be fed to young pigs if small quantities are given at first and increased gradually; pigs may even be fattened by this process. There is little data on gladiolus bulbs, but the author has been unable to trace any record of evil effects following their use.

In times of shortage the use of these bulbs as a cattle food is worthy of attention if the above mentioned precautions are taken. As these precautions vary with the different kinds of bulb it is necessary to be able to recognise to what variety the bulbs belong or, if the food is composed of a mixture of bulbs, the material used must be known. To facilitate this the author gives for each species of bulb short indications on the shape and size of the starch grains, the position of the hilum, etc. Micro-photographs are also given.

## BREEDING

1382 - Crosses Between the American Bison, the European Bison and Domestic Cow Made in the Zoological Garden of Askania-Nova (Government of Tauride, South Russia) (1). — IVANOV, F. and PHILIPTSCHENKO Jur. (Zootechnical Station of the Veterinary Service of Askania-Nova), in the *Zeitschrift für induktive Abstammungs- und Vererbungslehre*, Vol. 16, Pt. 1-2, pp. 1-18 + Figs. Leipzig, 1916.

During the summer of 1913, the authors studied the crosses made by M. F. E. FALZ-FEIN between the American bison (*Bison americanus*), European bison (*Bison bonasus*) and the domestic cow in his zoological garden at Askania-Nova; there were then 25, the most typical of which were described, with figures and measurements.

CROSSES BETWEEN AMERICAN BISON AND EUROPEAN BISON. — According to the authors such crosses have not been previously made save at Askania-Nova. There were adult hybrids (2 5-year old males and one 4-year old female, "Sanka"), produced from a male European bison and a female American bison. In 1911, the female "Sanka" was mounted by a European bison, and produced a heifer calf in 1912. Next crossed with a American bison × European bison hybrid, she gave, in 1913, a bull calf; this represents the  $F_2$  generation of the cross between American and European bison. The progeny of the female "Sanka" are still too young to be used in the research.

The American × European bison hybrids have, as regards their exterior a form intermediate between that of their parents. The head, as regards the hair and fringe on the throat resembles that of the American bison rather than that of the European one. The hump is smaller than in the American bison and its sweep to the head is less stiff and is more similar to the European bison. The resemblance of the animals to the European bison holds good also for the hind-quarters. The tail is of intermediate development. On the contrary the colour is like that of the European bison. As regards size and development the hybrids equal or surpass their parents. If their characters remain constant in future generations (which is not yet certain), the authors think these forms would have to be considered as a new species, which they propose to call *Bison falzfeini*, in honour of the breeder.

CROSSES BETWEEN AMERICAN BISON AND DOMESTIC COW. — On crossing a male American bison with a domestic cow, 2 males (now aged 14 and 13 years) were produced in the first generation as well as 2 females (13 and 11 years). As the 2 males ("Mischka" and "Selifon") were sterile they were castrated. The females ("Staraja" and "Podpalaja"), however, were fertile and on crossing either with American bison or domestic bulls, calved each time.

Of the two half-blood males, the authors only studied "Mischka", a typical intermediate form between American bison and domestic cow. The head, with a beard, strongly resembles that of the American bison. The tuft of hair at the lower part of the chest is also characteristic. The front legs have long hairs falling down to the knees. The horns are, however, like those of the mother (grey breed from the Ukraine steppes). The hump

(1) See also R., June 1914, No. 645. (Ed.)

is less pronounced than in the American bison, but is of the same type. The back and hindquarters are very like those of the American bison; the tail, intermediate between that of the American bison and that of the domestic cow, is shorter than in the European bison. The skin is of a dark colour.

Amongst the half-blood females, one ("Steraja", obtained by the cross American bison  $\times$  grey cow of Ukraine steppes) well shows the type intermediate between the parents, although its characters are less marked than in the male progeny. This animal resembles an ordinary cow much more than its brother does an ordinary bull. The head, which is bearded, resembles that of the American bison; the chest has a tuft of hair. The horns are those of the domestic cow. The thorax is shaped generally like that of the cow, and the hump is not pronounced. The hindquarters recall those of the American bison; on the contrary the tail is more like that of the cow. The colour is dark.

Another half-blood female, "Podpalaja", is clearly different from the preceding one, for it is the daughter of another American bison and a Shorthorn cow. It resembles the cow much more than the first, especially in the head. The beard and the tuft of hair on the chest are not much developed; the animal has a hump. The general colour is black, with white splashes on the belly and lower chest. HENSELER's observation that, in crossing Shorthorns with various wild forms (gayal, yack, etc.) the stripes sometimes seen in Shorthorns appear, has not been confirmed in this case.

The half-blood female, "Staraja", crossed with an American bison gave a heifer calf, "Slepaja", which is a  $\frac{3}{4}$  blood female bison. This animal is more like a female American bison than a cow. The head is that of the American bison, the neck and beard are strongly developed; the lower part of the chest had a heavy tuft of hair. The horns have, like these of the  $\frac{1}{2}$ -blood forms, the characters of the horns of the domestic cow. The hump is small and the hind-quarters resemble those of the bison. The colour is like that of the American bison but is lighter on the hindquarters.

On crossing the half-blood female "Podpalaja" with a Shorthorn bull a female ("Belaja") was obtained with  $\frac{3}{4}$  Shorthorn and  $\frac{1}{4}$  American bison blood. This animal so closely resembles the ordinary cow that its hybrid character cannot be determined at first sight. White colour. The only characters recalling the grandfather (American bison) are the hump and the tuft of hair on the lower part of the chest.

As regards temperament, all the hybrids (including the  $\frac{3}{4}$  Shorthorn cow) resemble the American bison most.

CROSSES BETWEEN EUROPEAN BISON AND DOMESTIC COW. — A half-blood male ("Herkules"), son of a European bison and a grey Ukraine cow, was sterile, and so was castrated, like the half-blood American bison. It resembled the European bison much less than the half-blood American bison does the American bison. The head is that of the cow but it has a beard and there is a tuft of hair on the chest. From the length and shape, the horns are of the bovine type. There is a hump, but it is smaller than in the European bison. The general constitution and colour make it an intermediate form between European bison and Ukraine cow.

A half-blood female ("Galka"), out of another European bison and another grey Ukraine cow, shows similar characters, and resembles rather the domestic cow. The head is that of the cow and the horns are those of the Ukraine cow. From the father are derived the beard and tuft of hair on the chest. The body is similar to that of the cow, but there is a well developed hump. The animal is coloured like the mother.

Another half-blood female ("Dunja"), out of a European bison and a grey Ukraine cow, has similar characters, but on account of the animal's youth they are less pronounced. The colour is not grey, but black.

The half-blood female "Galka" crossed with a European bison gave a bull calf ("Otboj") with  $\frac{3}{4}$  European bison blood. Allowing for its small size and other characters showing mediocre development, it is fairly distinct from the half-blood forms; it is most like the European bison. Both head and chest are very hairy, and the horns are of the cow-type. The hump and hind-quarters completely recall the European bison, while the colour is more like that of the cow. On the whole, this male resembles a European bison most.

A  $\frac{3}{4}$  blood female ("Golubka"), out of the  $\frac{1}{2}$ -blood female "Galka" and another European bison, has the same characters as the male "Otboj", but temperament, horns and colour are most like those of the European bison.

"TRIGENOUS" HYBRIDS BETWEEN EUROPEAN BISON, AMERICAN BISON AND DOMESTIC COW. — These are the progeny of the half-blood females (whose father was an American bison and mother a cow) crossed with a European bison. The males have not yet been used for reproduction, but they should be fertile as the sperm of one male contained normal spermatozoa. The females are certainly fertile. The authors describe some of the hybrids.

The male "Bjelmordij" differs from the half-blood American bison and the half-blood European bison by many characters. The head and strongly hairy coat recall the wild American bison, but in most of the characters it resembles the European bison. The beard and tuft of hair are as well developed as in the European bison, but the front quarters are less hairy than in the two species of bison. The horns are like those of the cow; the colour is dark, as with the European bison. This is a most original form, which most resembles the European bison (not as much, however, as the  $\frac{3}{4}$ -blood male "Otboj"), but showing a notable maternal influence.

Another male, "Petjka", is very similar to the previous one, but is smaller. The difference is seen in the fore-quarters (nape, neck, chest) which are more like those of the cow.

In a third male, "Dubass", the characters are the same as in the previous one; the hair of the head and fore quarters most resemble those of the male "Bjelmordij".

Another male, "Martin", has characters very different from the 3 previous ones. The hair on the body and fore-quarter is less developed, the horns smaller, but the hump is bigger and the tuft of hair is longer. As this animal is still young, some of its characters may change in time.

A female, "Lyssa", has, like all the females, less hair on the head,

so that it is more like an ordinary cow. The beard and tuft of hairs on the chest are well developed, however, and the horns resemble those of the European bison. On the whole, the characters incline more towards those of the European bison.

The author describes a "trigenous" female ("Tschubataja") which does not contain  $\frac{1}{4}$  cow's blood like the previous ones but  $\frac{1}{8}$ . The head is, broadly speaking, like that of a female produced by the cross American bison  $\times$  European bison. The horns are just like those of the American bison. The lower part of the chest and the upper parts of the fore-quarters are very hairy. The tail is like that of the European bison but is shorter; the part between the root and the tuft has the character peculiar to crosses between American bison  $\times$  domestic cow. On the whole, the female "Tschubataja" mostly resembles, not the pure blooded European or American female bison, but the female "Sanka" given by the cross American bison  $\times$  European bison. As "Sanka" has  $\frac{1}{2}$  American bison blood and  $\frac{1}{2}$  European bison blood and "Tschubataja" has  $\frac{1}{2}$  American bison,  $\frac{3}{8}$  European bison and  $\frac{1}{8}$  domestic cow, the resemblance of the two hybrids is easily explained.

In conclusion, the authors give measurements of 12 crosses (American bison  $\times$  cow, European bison  $\times$  cow, "trigenous" hybrids), but give the warning that they are not all reliable.

1383 - Comparative Yield of Cattle Before and After Fattening. — GOUIN, A. and ANDOUARD, P., in the *Comptes Rendus des Séances de l'Académie d'Agriculture de France*, Year IV, No. 18, pp. 556-557. Paris, 1918.

CATTLE

Under ordinary conditions the new-born calf requires less than 30 months to attain a weight of 500 kg., after utilising 2 600 kg. of food material.

The 500 kg. live weight does not represent more than 185 kg. of food stuffs, protein and fat, the surplus consisting mainly of water. The proportion of fat is then about 8 %, or 40 kg. out of the weight of 500 kg.

If the animal is fattened, suitable foods being available, the live weight should be increased from 500 to 600 kg. in 100 days, with a minimum of 25 % fat, or a total of 150 kg.

The 110 kg. (150-40) of fat thus gained required the following food material: —

- |   |           |
|---|-----------|
| 1) Material forming the fat, 100 kg $\times$ 2.27 . . . . .   | 249.7 kg. |
| 2) Work expended in forming the fat, of a value equal to twice that of the food. . . . .  | 499.4 kg. |
| 3) Maintenance of body for 100 days; average weight of 550 kg. corresponding to a surface area of 6.49 sq. decimetres . . . . . | 324.5 kg. |

Total . . . 1073.6 kg.

The daily food requirement is equal to 1.05% of the body weight; which agrees with the figures of the German school.

Thus, the unfattened bullock provides 185 kg. of food material for

human consumption, after consuming 2600 kg., while the fat bullock gives nearly 250 kg. more, against a consumption of 3 674 kg. of the same foods.

*Fattening increases the yield of the animal by 135 %, while the cost of its food only increases by 40 %.*

1384 - **An Experiment in War Time Beef Production, in Great Britain.**—WOOD, T B, in *The Journal of the Board of Agriculture*, Vol XXV, No 5, pp. 549-560 + 1 Table, London, August, 1918

The experiments described were undertaken to determine the minimum amount of cake required for winter beef production. The only previous direct experiment on the subject is one carried out at the Norfolk Agricultural Station in 1908, when 10 steers on a ration of 1 ½ cwt. of roots, 10 lb. of chaff and 1 lb. of cotton cake per head per day, gained 1 ¼ lb. in live weight per head daily for 20 weeks. During this period they produced 78 tons of dung of good manurial value.

The trials were carried out at two stations in Norfolk (Norfolk Agricultural Station, Little Snoring and Field Dalling), two stations in Scotland (Spencerfield and Craibstone), and three stations in Ireland (Ballyhaise, Athenry and Glasnevin). Two and a half year old steers were fed on as many roots and as much straw as they would eat, supplemented with only 1 ½ lb. per head per day of undecorticated cotton cake. Where possible the weights of litter consumed and of dung produced were recorded, and the animals slaughtered under such conditions that their carcass weights could be determined. Beyond these points the ordinary practice of the district in which the experiment was made was adopted, so that, though the method of feeding did not agree in every detail, the results show the increase in live weight which may be made by 2 ½ year old steers on a cake ration of 1 ½ lb. when the rest of the ration varies according to local practice.

Five of the results were extraordinarily uniform, showing an increase in live weight of from 8 to 10 lb. per head per week. In two cases (Norfolk Agricultural Station and Athenry) this rate was greatly exceeded (17 lb. and 15 ½ lb. respectively) possibly, in the first case, because a fair ration of good, long hay was given. At Glasnevin the rate of increase was much smaller (5 ¾ lb.), possibly an account of the small ration of roots. On the whole, the experiments showed that with a liberal allowance of roots and either good oat straw or hay, supplemented by 1 ½ lb. of cake per head daily, an average increase of about 1 ¼ lb. per head per day may be relied on in the case of good quality steers of 2 ½ years or more. It is not yet known whether younger animals would give similar results. In 15 to 20 weeks the animals will yield about 56 % of dressed carcass, which entitles them to be placed in the first grade. If kept in covered yards they will produce about 7 tons of dung per head during the feeding period.

The results leave no doubt that beef may be satisfactorily produced if the animals are given 1 ½ to 2 cwt. of cake. The yield of meat will probably be within 10 % of the yield obtainable with a normal ration of cake. The Scotch results suggest that beef can be produced from roots and straw with no cake at all, but the yield of meat will probably be reduced by a

further 5 % (a total of 15 %) below the yield obtained with a normal ration of cake.

The financial statements given show the cost of the stores, which amounted to 70% of the cost of the finished animal, to be by far the largest item in the total cost of beef production. If, therefore, stores can be bought at a reasonable price, say at 5s. per live cwt. below the selling price of beef, economic feeding should result in the production of dung at a reasonable price. The food is the next most important item and amounted to nearly 24 % of the total cost of production even with the low cake ration used. Labour and litter amounted to about 3% each. Though, from an economic point of view, it is desirable to economise in food and labour, by far the most important point is to economise in buying the stores, which should cost at least 5s. per live cwt. less than the price at which the finished animals will be sold.

1385 — “Woolless” Sheep as Butcher’s Animals in Cuba. — DE CASTRO, R., in the *Revista de Agricultura, Comercio y Trabajo*, Year I, No. 8, pp. 435-436 + 2 Figs Havana, August, 1918.

SHEEP

The author thinks that sheep rearing in Cuba should be intensified so that a more abundant supply of meat may be rapidly obtained and to profit from the many uncultivated or uncultivable areas still existing in the island. But as the wool breeds usually reared suffer either from the heat or ticks which hide in the fleece the author suggests the use of “Woolless” or “Barbadoes” sheep, originating in Africa, acclimatised at Barbadoes (Antilles) and introduced from thence into the United States. This breed is quiet, hardy, strong, and very prolific, since it lambs all through the year, producing from 1 to 5 lambs. They have no horns and the skin is covered with coarse, slightly wavy hairs. They seem excellently suited to warm climates. At Porto Rico they have given good results; in the experimental station of the island they have been crossed with the native wool breed, which is selected for meat production, and crosses have been obtained, in the majority of which the characters of the native race prevail, except for the fleece, which was absent.

1386 — Substitutes in Swine Feeding, in Canada. — I. ROTHWELL, [G. B., *Economical Substitutes in Swine Feeding*, in *The Agricultural Gazette of Canada*, Vol. V, No. 5, pp. 440-446 + 2 Plates. Ottawa, May, 1918 — II. TRUEMAN, J. M., War-time Hog Rations, *ibid.*, p. 479 + 2 Tables.

PIGS

I. — For several years numerous experiments in the feeding of pigs have been carried out at the Central Experiment Farm, Canada, and the paper under review gives a summary of the results obtained which may suitably be adopted under the food-shortage conditions brought about by the war.

Cottonseed meal, gluten feed, linseed oil meal and distillers' grains may possibly be obtained, though only in limited quantities. They give good and economical results when added to a basis maize, shorts, barley ration in the following proportions: — gluten feed 20 %, linseed oil meal 17 %, cottonseed meal 13 %. Good results were also obtained with 20 % of distillers' grains. An increase in the percentage of linseed and cottonseed

meal added causes protein poisoning, though as much as 30 % of gluten feed may be given. Maize oil cake, when procurable, is an excellent concentrate fed with shorts, or bran and skim-milk. Maize bran may be profitably fed to brood sows or fattening hogs, but not in quantities exceeding 20 %. Consistently good results were obtained with buckwheat screening which, when fed with skim-milk proved about equal to a standard ration of maize shorts and oil-cake.

It is not possible to vary very greatly the normal rations of young pigs. Skim-milk appears to be almost a necessity and cannot really efficiently be replaced by any other food. Tankage may, however, be regarded as a milk substitute. The best results were obtained when pigs were weaned without milk by supplying meal dry in a self-feeder, part of which was partitioned off and filled with dry tankage which was consumed as required. Water was freely supplied. The chief value of tankage is as a balance to grain. Middlings for the young pig may be replaced by 70 % shorts, 20 % maize meal and 10 % oil meal. With this, milk in some form is the one best food.

Feeding cut green crops to pigs is not advantageous on account of the labour it involves, and the fact that the feed soon becomes uneatable owing to exposure to the sun and soiling by the pigs, so that much waste occurs. Great advantage is, however, derived from pasturing. As a single pasture crop, alfalfa is unexcelled, though clover is almost its equal. Good results have also been obtained with rape as well as with heavy seedlings (3 to 3 1/2 bushels per acre) of barley, oats, or wheat. Of the cereals sown singly barley is the best pasture crop and, though a mixture of equal parts of barley, oats and wheat gives very good results, it is inferior to barley alone. A summer pasture of alfalfa, clover, or a spring-sown grain or grain mixture is a cheap self-harvested feed for growing pigs. Late summer and autumn pasture should be supplied by rape. An acre will pasture from 10 to 15 hogs in the growing season. An experiment showed the cost per 100 lb. gain to be reduced from \$ 5.30 in paddock feeding to \$ 3.54 in pasture feeding.

Skim-milk is the best single food for the growing hog, but buttermilk, fed fresh, is its equal. For a hog of 60 lb. or over, 400 lb. of skim-milk is equal to 100 lb. of meal. Whey also gives satisfactory results and, if fed fresh, 100 lb. will replace 19.2 lb. of meal. Skim-milk should not be overfed. With young pigs the best results are obtained with 1 lb. of milk to 2.5 or 3 lb. of meal; for a 100 lb. or more hog not more than 5 lb. should be fed daily. Milk should be fed sweet to very young pigs, but later there is little difference between sweet and sour milk so long as one or the other is fed consistently. Buttermilk and whey should be fed fresh.

Except in the case of the young pig, feeding twice daily is preferable to three times. Economy is effected by the use of a well-designed self-feeder; a combination of pasture, or successive pastures, with milk by-product and grain self-fed is specially recommended. During the pasture season if grain is self-fed 1 acre of land will carry an average of 4 000 lb. live weight of hogs. A series of experiments made in 1917 gave the following results for meal and milk trough-fed, meal and milk self-fed, meal and tank-

age self-fed, respectively :— Average daily gain, 0.85 lb., 1.05 lb., 0.53 lb.; meal eaten per lb. gain, 1.51 lb., 1.79 lb., 3.9 lb.; skim-milk per lb. gain 5.2 lb., 3.1 lb., —; cost per lb. gain 4.8 c., 5.3 c., 10.1 c.

II. — For three years the Nova Scotia Agricultural College has made experiments in feeding pigs on grain, skim milk and mangels. The results showed that gains can be made with a comparatively small amount of grain and with less total digestible nutrients than when grain is fed alone. The tables given show that 100 lb. of gain was made with an average of 148 lb. of grain, 900 lb. of skim milk and 110 lb. of mangels, containing 201 lb. of digestible nutrients. Quite a small amount of feed was given when the pigs were only 6 weeks old, but when they neared the age of 24 weeks (200 lb. or over) they consumed as much as 4 lb. of grain, 15 lb. of skim-milk and 4 lb. of mangels per day. The average daily consumption between the ages of 6 weeks and 24 weeks was 2.2 lb. of grain, 12.9 lb. of skim-milk, 1.6 lb. of mangels.

1387 — **Fish Meal as a Feed for Swine** (1). — ASHBROOK, FRANK G., in the *U. S. Department of Agriculture, Bulletin* No. 610, pp. 1-9. Washington, December 7, 1917.

The value of fish meal as a feed for pigs has been recognised for some years past, especially by Germany, which used it for this purpose to a far greater extent than any other nation. The experiments described were carried out at the Bureau of Animal Industry Experimental Farm, Beltsville, Md. to compare the value of fish meal and tankage as supplementary rations and to test the value of fish meal as a supplement to dried potato.

I. — *Comparison of fish meal and tankage as supplementary rations.* — Twelve grade Berkshires of uniform size, age, and breeding were used. The experiment was divided into two periods, a growing period of 112 days from weaning to fattening age, and a fattening period of about one month. The pigs were about three months old at the beginning of the experiment.

During the growing period the pigs were divided into two lots — 1 and 2 — of 8 and 4 pigs respectively. Lot 1 was fed 4 parts maize meal, 4 parts middlings and 1 part tankage, and Lot 2, 4 parts maize meal, 4 parts middlings and 1 part fish meal. Lot 2 made a greater daily gain per pig (1.31 lb.) than did Lot 1 (1.25 lb.), and at the end of the experiment the average difference in weight was 10 lb. in favour of fish meal. Lot 1 ate slightly less grain per pig daily (4.53 lbs.) than Lot 2 (4.80 lb.). There appeared to be no difference in growth or general development between the two lots, showing that there was little to choose between the rations.

During the finishing period the same 12 pigs were divided into 3 lots of 4 animals and fed as follows :— Lot 3, 4 parts maize meal, 4 parts middlings, 1 part fish meal; Lot 4, 9 parts maize meal, 1 part fish meal; Lot 5, 9 parts maize meal, 1 part tankage. Lot 4 made the highest daily gain per pig (2.16 lb.), Lot 5 the next highest (2.00 lb.) and Lot 3 the lowest (1.91 lb.). The grain consumed per 100 lb. gain was :— Lot 5, 462.00 lb.; Lot 3, 421.00 lb.; Lot 4, 393.00 lb. It will be seen, therefore, that the best results were obtained with 9 parts maize meal + 1 part fish meal.

See also R. Dec., 1916, No. 1301; R. June, 1917, No. 565. (*Ed.*)

2. — *Fish meal as a supplement to dried potato.* — Twelve high-grade Berkshire pigs between 5 and 6 months old were divided into four lots of three pigs and fed the following rations: — Lot 1 (check lot), 6 parts maize meal, 1 part tankage; lot 2, 6 parts dried pressed potato, 1 part tankage; Lot 3, 6 parts dried pressed potato, 1 part linseed oil meal (old process); Lot 4, 6 parts dried pressed potato, 1 part fish meal. The average daily gains were: — Lot 1, 1.57 lb.; Lot 4, 1.32 lb.; Lot 3, 0.91 lb.; Lot 2, 0.80 lb. The rations fed per 100 lb. gain were: — Lot 1, 403 lb.; Lot 4, 428 lb.; Lot 3, 584 lb.; Lot 2, 605 lb. The most rapid and economical gains were made with 6 parts maize meal + 1 part tankage, though those made with 6 parts dried potato + 1 part fish meal were not much inferior.

At the end of the experiment the heaviest animal from each lot was killed to determine the quality of the flesh and fat and the degree of finish. In no case did the meat have any fishy smell or taste.

These results show that, where it can be obtained at a reasonable price in suitable quantities, fish meal, if used in proper proportions, should become one of the most popular and economical supplements for feeding pigs.

## POULTRY

1388 — *The Part Played by the Egg Shell of the Hen in the Formation of the Chicken's Skeleton During Incubation.* — DELEZENNE, C. and FOURNEAU, E., in the *Annales de l'Institut Pasteur*, Vol. XXXII, No. 9, pp. 413-429 + 7 Tables. Paris, 1918.

It is known that the fresh hen's egg contains little lime (CaO), usually not more than 35 mgm. for an egg weighing 60 gm. It may, therefore, be asked: — 1) how can the chick form its skeleton with so small a quantity of lime; 2) if the chick contains more lime than was present in the interior of the egg during incubation, whence has it obtained it? A review of the chief work done on the subject (PROUT, GORLEY, VOIR, PREYER, VAUGHAN and BILLS, TANGEL) show how greatly the opinions vary as to the part played by the egg shell in the formation of the chick's skeleton: some refuse to admit it, while others take it as proved.

Owing to these diverging opinions, the authors have reopened the question. They have estimated the lime in the contents of a large number of eggs. These, placed in an incubator, were removed successively on the 10th and 12th day of incubation (when ossification of the skeleton begins), then regularly each day from the 14th to 21st day (hatching). To control the results the authors used eggs other than these of the hen, such as duck and peahen. The results, given in tables, show: — 1) the weight of the fresh egg; 2) the lime in the contents of the egg on the day of sampling; 3) the lime in proportion to 100 gm. of whole egg weighed at the moment of laying; 4) for certain samples, the total percent of phosphorus in the entire egg.

The results are very clear and lead to the following conclusions: —

1) The lime in the content of the egg increases about 500 % during the whole time of incubation. This increase begins to be traceable about the 10th and 12th day of incubation, is very marked about the 16th and 17th days and then continues regularly until hatching.

2) In the unfertilised hen's egg put to incubate, the % weight of lime

after 21 days is the same as in the fresh egg ; no trace of lime passes from the shell to the interior of the egg.

3) In peahen eggs, the increase in the lime content during incubation was 500 %, while, in duck eggs, it was slightly below 400 %.

4) The phosphorus does not increase during incubation.

These experiments clearly show that the physiological role of the egg-shell of birds consists in supplying the embryo with a lime reserve, which the embryo utilises during incubation in a way as yet unexplained. But it may be said that "the modifications undergone by the vitellus and albumin during incubation take place in a regular rhythm, during which a substance is freed in determined amounts and which has the power of dissolving a determined amount of the lime of the shell".

This substance might be an acid, a sugar, or allantoin. But the authors think that the solution may be obtained by a minute analysis of the amniotic liquid, which, in fact, about the 17th day of incubation, at the moment when the solution of the lime increases, is alone in contact with the shell through the egg membrane.

1389 - **Final Report of the Fourteenth Egg-Laying Competition Held at the Queensland Agricultural College, Gatton, from April 1, 1917 to March 31, 1918** (1). — *Queensland Agricultural Journal*, Vol. IX, Pt. 6, pp. 213-225 + 10 Figs. Brisbane, June, 1918.

In the 14th competition 438 birds competed, 318 in groups of 6 and 120 singly. The advantage of this last method was again confirmed and the group system must be considered obsolete. The weather conditions were very unfavourable and the quality of the food poor. The hens showed a strong tendency to brood, perhaps as a result of the continual wet weather. In short, the results were not very satisfactory. The average yield per hen was the lowest yet recorded in the Gatton competitions. The total was 83 868 eggs or 191.5 per hen in one year. The maximum yield from the light breeds, represented by White Leghorns only, was 1652, or 275.3 per head. The first place among the heavy breeds was taken by Black Orpingtons with 1470 eggs or 245 per hen. Two new records were made — one Black Orpington laid 335 egg in 365 days and one group of six White Leg-

(1) For the results of the competition held from April 1, 1913, to March 31, 1914, see R. 1915, No. 82. In the competition held from April 1, 1914 to March 31, 1915, for which were entered 240 hens, including 192 White Leghorns, 54 202 eggs, or an average of 226 per hen, were laid throughout the year. The first three groups of 6 hens gave 1545, 1544 and 1534 respectively. Only four groups gave less than 1200 each (*Queensland Agricultural Journal*, Vol. III. Pt. 6, pp. 241-244. Brisbane, June, 1915). In the competition held from April 1, 1915 to March 31, 1916, for which 53 groups of 6 hens (318 hens) were entered, the total number of eggs laid was 70 848, or an average of 222.8 per hen. The first three groups (White Leghorns) gave 1530, 1530 and 1481 eggs respectively. Only six groups gave less than 1200 eggs. These competitions showed the light Mediterranean breeds to lay best. In competitions they should, therefore, be separated from the less active large Asiatic breeds. The necessity of breeding hens with a view not only to their laying capacity, but also to their general vigour and trueness to type was likewise shown. (*Ibid.*, Vol. V, Pt. 6, pp. 316-322. Brisbane, June, 1916) (*Ed.*)

horns laid 1661 eggs, or 277 per hen in one year. In both cases the birds were disqualified for prizes because the eggs were below the standard of 24 oz. the dozen. The competition showed the necessity of not sacrificing the size of the egg to the size and vigour of the hen and, consequently, to fertility.

The food consumed by the 438 hens throughout the year was: — wheat 296 bus., maize 42 bus., hulled oats 15 bus., skinless barley 9 bus., pollard 420 bus., bran 196 bus., oilcake 4 cwt., desiccated meat 2 cwt., bonemeal 1 ½ cwt., dried blood 4 ½ cwt., green lucerne, and soup meat.

## BEE KEEPING

1390 - **The Artificial Feeding of Bees with Pollen.** — USAY, J., in the *Illustrierte Monatsblätter für Bienenzucht*, Year XVIII, No. 5, p. 35. Vienna, 1918.

It is known that in spring bees use a large amount of pollen for feeding the hive. As, in many countries, flowers are rare at this period and the workers are impeded by the bad weather, the author advises the provision of pollen for the bees. This was suggested to him by the fact that many beekeepers spread in front of their hives flour, which is eagerly gathered by the bees. At the flowering season of resinous trees, which produce abundant pollen, the author shook cones over a box cover, thus obtaining an abundant supply of pollen, which he kept in a dry room till the following spring. When this dust is spread on a board in front of the hive in fine weather the bees immediately collect it. The author has observed no ill effects as a result of this food.

## SERICULTURE

1391 - **The Creation of an Interministerial Silk Committee, in France.** — *Journal Officiel de la République Française*, Year L, No. 262, p. 8417. Paris, September 26, 1918.

By the decree of September 20, 1918, there was created in France an Interministerial Silk Committee controlled by the Minister for Commerce and composed of 21 representatives of the various Ministries as well as of the silk trade and industry.

Its functions are (art. 1):—

- 1) To suggest, centralise, co-ordinate and indicate measures for assuring to France a supply of silkworm eggs, raw silks, worked silk, silk by-products and articles made in silk;
- 2) To establish, in agreement with those using silk in its different forms, and with traders and manufacturers interested, those products that should be given priority and to indicate the relative urgency;
- 3) To indicate measures to be taken to provide for such needs according to the orders of priority;
- 4) To carry out the same study and exercise the same control for artificial silk;
- 5) To suggest any other action that may be required.

1392 - **Influence of the Breed of the Eggs on the Cleanness of Raw Silk.** — FURUMOTO, J., in the *Bulletin de l'Association sericicole du Japon*, Year III, No. 1, pp. 1-4. Tokio, April 15, 1918.

For a long time Japanese silk has been criticised for its too large number of knots. From this point of view Japanese silk is much inferior to

that produced by other countries, not only France and Italy but also China.

There are many causes that combine to produce knots and down on Japanese silk, but the chief one is the damp air in that country. Thus when winding or drying and preserving the cocoons in Japan it is highly necessary to maintain a very even temperature, still more than in continental countries such as France, Italy and China, where the atmosphere is generally dry. As this has been done the defects have been found to have largely diminished.

The author (engineer at the Yokohama Silk Conditioning House) gives figures showing the variations in the numbers of knots between 1900 to 1916 inclusively. On an average, in 1900, out of 500 metres of thread there were 3 knots and 265 downy spots, while in 1916 there were only 0.9 and 146 respectively.

The number of large and small knots tends gradually to diminish, which shows a great progress in the art of spinning. The number of defects began to decrease especially after 1912.

The author thinks that this good result may be due mostly to the propagation of first generation hybrids, which is so marked of late years that it constitutes a veritable revolution in the Japanese silk industry.

So as to test this hypothesis the author divided the silk-producing regions into 2 classes, one including the regions where first generation hybrids are in favour, the other including those where cocoons produced from native eggs are still numerous, and he has compared the silk produced by the 2 classes as regards its cleanness. There was a decrease of 41.9 % of knots in the regions where hybrids are more widely diffused than native eggs and a decrease of 32.8 % in those regions where there is still a fairly high proportion of native eggs.

1393 — On the Possibility of Rearing the Manatee as a Food Animal in French West Africa (1). — MENEGAUX, A., in the *Comptes rendus des Séances de l'Académie d'Agriculture de France*, Vol. IV, No. 24, pp. 698-705. Paris, July 3, 1918.

OTHER  
LIVE STOCK

Attention is first called to the experiments made by Dr. BELL in 1916 and 1917 in Florida on rearing the American manatee (*Manatus latirostris*) in half-stabling in the lagoons, experiments showing that this animal might by very valuable as a butcher's animal.

The African species, or Senegal manatee (*M. Senegalensis*), inhabits all the estuaries and lagoons from the mouth of the Senegal up to the river Cuenze, in Angola and often going considerable distances up the rivers. It thus occurs on all the coasts of Gambia, Liberia, Ivory Coast, Cameroons, Gabon, in the Ogoové, Congo and even in lake Tchad. Morphologically it is little different from the American manatee, while the habits and structure

(1) See R., Dec., 1917, No. 1200. In that article read "manatee" instead of walrus. The walruses or Trichechidae are arctic and circumpolar Pinnepedia. They are carnivorous. The manatee, however, belongs to the Sirenia (e. g. *Manatus latirostris* of America and *M. senegalensis* of Africa); they live in the fresh waters along the Atlantic coasts of America and Africa; they are herbivorous. See *Cambridge Natural History*, Vol. X, Mammalia. (Ed.)

are identical; however, no specimens have been reported so large as those in America. Its food plants are not sufficiently precisely known, but as *Cymodocea nodosa* occurs in all the lagoons and estuaries where it dwells, there is reason to suppose, by analogy with what happens in America, that it browses exclusively on that plant. In captivity it eats vegetables such as lettuce, cabbage, celery tops, baked apples, spinach, and even bread.

The African manatee measures from 10 to 20 feet and its weight varies from 660 to 1650 lb. for old males. These animals are monogamous; the period of gestation lasts 8 months and the young are born in shallow lagoons where the mother can breathe without being forced to come to the surface. The family consists of 4 individuals: the adult pair, one half-grown and a calf, generally born in the autumn.

The meat of the manatee, like that of the dugong, and to the contrary of many new meats, has been liked by all those who have tried it; it has been compared to veal cutlets, to pork or tender beef; it is white, delicate and of a delicious taste; it is the meat of an herbivorous animal. When it is salted it is like excellent bacon with good keeping properties.

The tail, especially that of young animals, is a great delicacy when pickled and eaten cold; the sucking animal gives very delicate meat. The whole body is surrounded with a  $1\frac{1}{2}$  in. layer of blubber, which gives an oil said to be equal to that of cod liver oil, having, moreover, the advantage of being odourless, tasteless, clear, and limpid as well as of not going rancid; it, however, contains no iodine. The bones are very compact and could replace ivory. Some 85 % of the body of the manatee can be used as food; a manatee yields almost as much eatable meat as a steer.

The African manatee can be reared practically and it is to be hoped that the Governments of the African colonies will study the subject. In the first place it would have to be found out whether *Cymodocea nodosa* exclusively forms the food of these animals; if it contains iron, like the American species; where it best lives and if such are places where the manatee would live by preference. It would then be quite easy to fix on lagoons where stabling would be possible without too great cost, whether for starting or up-keep.

## FARM ENGINEERING.

AGRICULTURAL  
MACHINERY  
AND  
IMPLEMENTS

1394 - The Function of Agricultural Engineers as regards the Makers of Power-Farm-  
ing Machinery. — CORÉ, Lieutenant, in *Produire*, No. 5, pp. 158-160 + 1 Fig. Paris, July  
5, 1918.

Considerations of a purely agricultural order are of capital importance to makers and it appears from a perusal of technical treatises on power farming that mechanical engineers have not had such detailed information as would allow them to take such considerations into account in their researches. It is indispensable that the makers should be supplied as early as possible with all the desired information so as to avoid feeling their way or following a line that would only lead to disappointments to farmers. Many essential points have yet to be cleared up in this order of ideas.

The supporters of power farming are divided into two groups, and it is at present impossible to say which will vanquish the other. For the one, the problem of power farming consists in the simple substitution of mechanical for animal traction in various ways, while preserving the principle of the plough sock as well as the present instruments of cultivation. For the other, on the contrary, the question is that of replacing the work of the plough share by that of tools, the nature of which does not seem very clear any more than that of the movements by which these tools should be worked.

For the first group, supporters of the plough, it is absolutely necessary to turn the earth to a certain depth before winter. The second group insist that the earth should not be turned, but pulverised to a great depth. This theory, containing the principle of "dry farming" seems to be most applicable to very dry soils and new soils.

Makers can, therefore, justly ask the agricultural experts to say which of the 2 methods, ploughshare, or special parts driven mechanically either with a rotary or alternately rectilinear movement is the best. So far it seems that both methods are of interest. If the experts cannot decide that one method is certainly better than the other, it ought at any rate to be possible for them to state in what regions and under what climates one or other of the methods is the more suitable from the purely agricultural standpoint. They could then easily deduce over what areas one or other of the methods should be employed; the makers would then be able to decide the importance of the outlets opening for them in the two cases, and run their works accordingly. The engineers have yet to provide them with more precise detail as regards indirect traction by cable and windlass as well as regards direct traction by a motor-tractor, the compression of the soil, and the working speed of the plough. In the case when the ploughshare is to be replaced by working members, driven through suitable mechanism, by an engine serving at the same time to propel the machine, the problem appears still more difficult. The author thinks that machines of this kind would only succeed in so far as the work they do (crumbling the soil) corresponds to the requirements of the land. If agreement is obtained on this principle, it remains to be settled how such crumbling should be carried out and to what degree of fineness and if the machine may not be required to have a digging action, all indications that can only be supplied by the farmer. According to the author light tractors of the Caterpillar type, in particular, seem indicated as immediately furnishing the best provisory remedy for the agricultural crisis. Tractors of the Caterpillar type have been used in large numbers for military purposes and have shown their worth. However, these machines could not provide a final solution of the problem of power farming; as such a solution could only be reached through long researches.

1395 - A Tractor School in Illinois, U.S.A. — *Farm Implement News*, Vol. XXXIX, No. 31, p. 18. Chicago, August 1, 1918.

The Farm Mechanics Division of the University of Illinois announces a series of short courses in tractors to be held between October 15, 1918 and

March 17, 1919. The schools will be held for 2-week periods, the number of pupils being limited to about 50. It is hoped to recruit the pupils from tractor owners, implement dealers and automobile dealers. The tuition will cost 2 \$ a week. The school will be under the direction of Prof. E. A. WHITE, instructor in farm mechanics.

1396 - **Restrictions on the Manufacture of Farm Implements in the U. S. A.** — *Farm Implement News*, Vol. XXXIX, No. 29, pp. 48-49; No. 30, pp. 12-13. Chicago, July 18 and 25, 1918.

The Conservation Division of the War Industries Board of the United States has published a schedule of farm implements and their parts which are to be eliminated so as to economise in labour and material.

The eliminations thus made apply : — 1) to grain drills and other seeding machines, fertiliser drills (only one size of broadcast fertiliser distributor can be made) ; none of these machines may be manufactured after Nov. 1, 1918; 2) partially to portable grain elevators, only one type being allowed; 3) to several types of ploughs, after Dec. 31, 1918, and especially to left-hand ploughs, which may not be made after July 1, 1918 (the sulky and gang ploughs are limited to a few types the most in demand) ; 4) to harrows, which are restricted to U-bar, channel bar and wood bar types; 5) to disc-harrows, save to 16-in. and 17-in. sizes, and those 4, 5, 6, 7, 8, 9 and 10 ft. long, the same applying to engine disc harrows. Tools used for raising sugar cane are not included in the list. The manufacturers are obliged to maintain and assure an adequate supply of repair parts of all types, sizes or types of implements becoming obsolete through these eliminations in order that farmers may be assured of necessary spare parts for a time in excess of the normal life of the various implements. Other eliminations are being planned for harvesters, mowers and rakes. From an inquiry made, it seems that one-horse mowers should be limited to the 3 ½ ft. bar type and that hand dump hay rakes should be no longer made as well as all sizes of binders save those of 6-ft., 7-ft. and 8-ft cut. The construction of 2 row drills for maize and beans is limited to 2 types, one 28 in. to 3 ft. 8 in., and the other 32 in. to 4 ft.; these are the maximum and minimum adjustments, intermediate ones being optional with each maker. Detailed regulations for the manufacture of maize drills, and cultivators of various types are also given.

1397 - **National Power Farming Show at Salina, Kansas, U. S. A.** — *Farm Implement News*, Vol. XXXIX, No. 32, pp. 30-48 + 72 Figs. Chicago, August 8, 1918.

The national power farming show was held from July 29 to August 2, 1918, at Salina, Kansas, U. S. A., 48 makers with 232 tractors taking part. The ploughing depth was only 4 inches. Half of the ploughs pulled were 3-bottom ploughs, the remainder having 2 and 4-bottoms. Disc ploughs were shown; it appears that the use of disc ploughs has much increased in Kansas of late.

This demonstration was the first of a national character where official prony brake tests were made. The tests began 4 days before the show was opened; the results will not be published, but each maker receives a report

covering the tests of his tractor or tractors, and which he can use as he thinks fit, except that he can not publicly make a comparison between his own figures and those relating to other machines. The Belgian, French, Italian and Peruvian governments sent official representatives to attend the show.

Technical reports will be published later showing the value of the show.

**1398 - Tests of the Cleveland Tractor at Montpellier, France.** — CLARON, C., in *Le Progrès Agricole et Viticole*, [Year XXXV, No. 23, pp. 150-153 + 1 Fig. Montpellier, August 18, 1918.

As the Cleveland tractor (1) had arrived too late to take part in the tests of vine cultivation by power at Montpellier, France, in 1918, it was tested separately at the School of Agriculture of that town.

During the tests in April, 1918, at Noisy-le-Grand, the tractor, on account of its small dimensions and the fact that it can turn in its own length was considered to be suitable for work amongst the vines. In tests among vines at Roche-de-Bran, near Poitiers (2), this tractor gave good results in rows 6 ft. 6 in. apart.

In this chain-track, 12-20 HP. tractor, the two driving wheels have been replaced by two pinions, which form the rear part of the machine and carry two chain tracks running over pulleys in front. Each track is 18 in. long and 7 in. wide and carries 44 teeth which act as spuds though not cutting. Owing to the gripping surface of each chain track (35.7 sq. decimetres) the tractor can work in any kind of soil. If the tracks wear on the macadam when used on the road, they have the advantage of not requiring, as do other tractors, a set of spuds or strakes to be put on to provide grip. The author says that, of all the tractors he has tried, the Cleveland is one of the easiest-starting ones. It is easy to drive and can turn in a circle of 143 in. diameter.

The tractor was tested on July 17, 1918, when it towed a 3-furrow EMERSON plough in a field that had been harvested a few days previously with a  $\frac{9}{16}$  CASE tractor towing a "La France" binder. The soil was in good condition, but dry and the plough worked shallowly from 4 to 7 in.

**RESULTS OF THE TRIALS.** — No dynamometric tests were made, but by comparison the author was able to estimate that the 3-furrow plough required a tractive effort of 550 kg.; when lifted it required about 70 kg.; the traction per sq. decimeter thus works out at about 37.6 kg. The absence of a coupling between tractor and plough was regrettable as it would have saved numerous shocks to the machine. When ploughing the machine ran at about 2.3 miles per hour; in the long run the motor might suffer from such violent work.

The running tests gave the following results:— revolutions per minute, 720 slow and 1 550 loaded; average depth of ploughing, 5 in.; average width, 38 in.; furrow length, 417 ft. going and 394 ft. returning; total journey, 1 621 ft.; total area ploughed, 5 167 sq. ft.; time required for ploughing, 5 minutes 7 seconds; time required per acre, 89 minutes; petrol consumed

(1) See R., October, 1918, No. 1145. (Ed.) — (2) See R., Nov. 1918, No. 1267.

during trial, 0.239 galls ; petrol consumed per acre, 1.9 galls ; petrol consumed per 1000 sq. ft. ploughed, 1.03 galls ; soil turned per lb. of petrol, 1 263 cu. ft.

On order to calculate the time required to plough an acre, the totals of the various stoppages during ploughing have been calculated, according to the practice at the Montpellier School, at  $\frac{1}{4}$  hour of the total time necessary for the work. The results are excellent, according to the author, and allow the Cleveland to be classed among the best machines as regards its yield. Long duration tests will be carried out with this tractor near Montpellier. As the new type of chain tracks used in the Cleveland is so ingenious it is possible that they might decrease the wear for which chain tracks are blamed. The author considers that the Cleveland constitutes a distinct progress and should be considered amongst the chief tractors on sale in France at the present day.

1399 - **Couplings for Tractors.** — RINGELMANN, M., in the *Bulletin de la Société d'Encouragement pour l'Industrie Nationale*, Year CXVII, Vol. CXXX, No. 4, pp. 112-114+3 Figs. Paris, July-August, 1918.

The author's researches on couplings have shown that a saving in traction for the engines can be made of 33 to 54 % on the starting effort and 10 to 30 % on the average tractive effort. If the use of couplings reduces the fatigue of animate engines it acts similarly on inanimate engines, for

SHANKLAND coupling.

which its use is shown by a saving in fuel estimated by the author at from 2 to 3s. per acre.

The author describes: (1) the coupling made by the "Ateliers BRILLÉ", 28, boulevard de Villers, Levallois-Perret (Seine), France. This spring buffer blocks at a pressure of 2 200 to 2 640 lb.

(2) The buffer proposed by M. D. SHANKLAND, Great Clyde St., Glasgow (1). With this coupling the tractor can be separated from the plough at the end of the journey. The pieces 1 of the figure reproduced, forming part of the shackle 2, carries a slotted member in which fits the part 4 united to the bolt 5 holding the spring 6 which is adjusted with the screw and lock-nut 7; the spring 6 is centered by means of the nuts 7.

The attachment to the opposite side of the shackle 2 is by means of the hook 10 and the iron-pin 9 held in place by 2 keys. As the spring is com-

(1) See R., May, 1918, No. 566, Patent 112579 of the United Kingdom.

pressed by the pull, the pin 9, pulling the bolt 5, leaves the shoulder *a*, guided by two slits cut in the cheeks of part 1; the slits, at first straight, end in a curve shown by the dotted line 3. At the end of the journey of part 4, a little before the spring 6 is completely blocked, the pin 9 falls from the slits 3 and the hook 10 becomes free from part 4 and shackle 2; the tractor is then automatically detached from the plough thus avoiding breaking parts. The author has already remarked (1) on the similar automatically-unhooking coupling on the Hourioux system. All the devices for automatic unhooking are advisable provided they are neither too heavy, nor too complicated to make and consequently too highly priced or out of proportion to the desired aim.

1400 - **Harvesting with a Tractor.** — RINGELMANN, M., in the *Bulletin de la Société d'Encouragement pour l'Industrie Nationale*, Year CXVII, Vol. CXXX, No. 4, pp. 97-101 + 5 Figs. Paris, July-August, 1918

M. F. BOUCHARD, director of the Dieufit estate at Bellon-en-Houlme

Plan of tractor attached to two binders.

(1) See *Culture mécanique* by M. RINGELMANN, Vol. I, p. 16. Librairie Agricole de la Maison Rustique, Paris, 1913. (Author)

(Horne), France, has adopted a device shown on the appended figure for hitching 2 binders to a 16 HP. MOGUL tractor (1).

The shaft *a* of the first binder *A*, working on the width *yy'* is attached to the right of the tractor *T* running along the side *y* of the field.

At the rear of *A* is a cross-bar *mm* whose end *m* is held in permanent position by 2 braces *t* and *t'* which prevent the angle *anm* from opening; the tie-rod *t'* passes under the platform of the binder *A*. Near *m*, at the desired point, the shaft *b* is attached of the second binder *B*, which can thus turn round the point *m* and the whole machine moves in the direction shown by the arrow on the side *R* to be harvested, cutting over the width included between the parallels *y* and *y'*.

The mounting used for 2 MacCormick binders, cutting 59 in. to the right hand, enables them to turn in the smallest turning radius of the tractor. M. BOUCHARD turns outside to the right without cutting; the tractor begins to turn when the second binder is at the corner of the field to be cut. Before the machines enter, the field is cleared on a width of 22 to 26 ft. The author thinks that less width could be freed if the first turns were done with a single binder, even by only cutting the 2 long sides of the field; the second binder would be attached after sufficient space has been cleared.

With a 59 in. cut, on a width of 95 in., M. BOUCHARD cut as much as 7 176 to 7 296 sq. yd. per hour; a driver is required for each binder. The author recalls the MASSEY-HARRIS device for attaching a binder to a tractor. Instead of the ordinary pole used with a team, a frame in the shape of an isosceles triangle is fixed in front of the binder, the summit of the triangle pointing towards the carrying and driving side of the binder; the forward base of the isosceles triangle carries a horizontal screw working in a nut fixed to the shaft through which the machine is hauled. The screw is moved by a bevel gear and a pointed shaft ending in a wheel by the driver. The frame is prolonged under the binder frame by a bar to the back end of which the pole of the next binder is attached.

#### 1401 - Simultaneous Harvesting and Breaking-up of the Stubble with a Tractor. —

*Le Génie Rural*, Year X (New Series., No. 24), No. 84, pp. 7-8 + 2 Figs. Paris, 1918.

To hitch a 13-time MASSEY-HARRIS cultivator to a binder towed by an AVERY tractor (2), M. GRATIAUX, of Epervon (Eure-et-Loire), France, uses an iron bar 6 ft. 6 in long bolted on to the shaft of the binder and clamped behind on the binder frame. On the steering device of the cultivator are bolted 2 flat irons joined by a bolt to the end of the bar projecting from behind the binder. This device is to leave steering free in a vertical direction but to render it rigid horizontally, so as to allow the binder and cultivator to back if required.

M. L. DANCAUD, of Levet (Cher), has designed a device similar to that just described and which is also intended to carry out 2 operations at once. Although less simple than the former, as it requires a special tractor, M. DANCAUD's device is said to constitute a great progress in mechanical

(1) See R. February, 1918, No. 201. (Ed.)

(2) See R., 1917, No. 945 (Ed.)

traction. Instead of towing the binder by a tractor and hitching a stubble breaker behind the binder the new arrangement makes it possible to attach the binder in front of the tractor and the stubble breaker behind. Thus

Plan of DANCHAUD tractor.

the tractor pushes one machine and pulls the other. One man can drive the tractor and supervise the working of the 2 machines. Moreover, as the binder is in front of the tractor, it can cut a greater width as there is no

risk that the tractor will pass over the uncut crop. Other machines that work suitably together can be used to replace the binder and stubble breaker (hay mower and hay maker, or one binder in front and another behind the tractor.

In addition the device is well suited to the direct driving of the working parts of agricultural machines in general and specially of binders and reapers by the tractor engine. The appended design gives a plan of the invention. The apparatus includes a frame on which is mounted the engine with the gear, drive and controls. The frame is mounted on two driving wheels 2 in front and 2 steering wheels 3 in the rear. In front of the frame two arms 5 are mounted on the axle 4 and carry a shaft 6 for connecting with the machine to be driven or partially or totally supported.

In the rear of the frame, the arched pieces 7 of the steering gear are mounted. These pieces have their end joined to a draw bar 8 for such agricultural machines as have to be drawn by the tractor.

**1402 - Log Saw.** — MANRIN, G., in the *Journal d'Agriculture pratique*, Year LXXXII, New Series, Vol. XXXI, No. 18, p. 355 + 2 Figs. Paris, September 5, 1918.

Log saws made by M. BIAUDET FORTIN, of Montereau (Seine-et-Marne), France. In the "Rustic" type of log saw the circular saw is mounted on ball bearings; the saw is 24 in. in diameter and is protected by a cover. The log to be cut is placed in a rectangular cradle whose frame is mounted on a horizontal axle placed lower down. Once the log is placed in position all the man has to do is to push it towards the saw, pressing more or less according to the hardness of the wood so as not to stop the machine or to make the driving belt slip.

To provide the military type of log, the War Administration uses similar saws driven by a petrol motor, the whole being carried on a truck mounted on 4 cast-iron rollers. The motor and its accessories are at one end of the truck, behind the water tank mounted on the tool box; the fuel tank is strengthened by oblique stays hooked to its upper edge and fastened below to the truck. The saw, whose frame is made of steel angle-irons, is bolted to the other end of the truck above the front wheels.

**1403 - An Improvised Pasteurising Plant.** — BALLHAUSEN, O. C., in the *Agricultural Gazette of New South Wales*, Vol. XXIX, Pt 2, pp. 128-130 + 1 Fig. Sydney, February 2, 1918.

An ordinary rapid pipe-cooler with 16 2-in. pipes, and 42-in. high and 54-in. long, has been transformed into a pasteurising plant by Mr. J. McDERMOTT, the Manager of the Bonalbo Dairy Company. The cold brine is replaced by hot water and live steam which are pumped through the pipes. To prevent the cream splashing on falling onto the heated pipes, two tinned sheets, 24-in. high and 54-in. long, were fitted close against the pipes. The top edges of the sheets are bent outwards while the lower edges are bent inwards. A depth of 18-in. at the bottom of the heater is not covered by the sheets, the idea being to allow the gases and steam arising from the heated cream to escape.

The cream passes off the heater into the tanks at from 160 to 170° F;

450 gallons an hour can be heated to 160° F. Cooling is carried out in the same machine, bang continued till the cream is at 48°F. The day after the cream is churned at the same temperature.

Mr. L. T. MAC INNES, the Acting Dairy Expert, found the butter made from cream thus treated to be of choicest grade and to have no cooked flavour at all.

**1404 - Equipment for the Commercial Evaporation and Drying of Fruit in the U. S.**  
A. — BEATTIE, J. F. and GOULD, H. P., in the *U. S. Dept. of Agriculture, Farmers' Bulletin* No. 903, 60 pp. + 22 Figs + Bibliography of 20 Publications. Washington, September, 1918.

Although intended for those who contemplate engaging in the art of drying or evaporating fruits or vegetables, this bulletin contains very useful information for all who wish to dry fruit for home use. The authors describe the various types of equipment for drying fruits or vegetables, as well as the methods of heating that are most used and which have given the best results taking their simplicity and economy into account.

The driers used in the apple-drying industry of the eastern portion of the United States are for the most part of the kiln type. The almost universal use of this type is due to the low first cost of the kilns and the small amount of labour required to operate them. In an area of western New York there are some 2 000 commercial driers, 500 being large plants; about 75 % of the evaporated apples produced in the eastern portion of the United States come from this area. Other States, such as Virginia, Illinois, Arkansas and Missouri, also produce considerable quantities of evaporated apples, most of which are prepared in kiln driers.

The modern kiln consists of a structure two stories high, the ground floor being occupied by the furnace while the second floor serves as the drying room. The construction of the building, the air ducts, the drying floor, the drying plant, are all described in detail, plans and figures being also given.

The steam-heated cabinet drier has been found to be a more efficient type as well as being adapted for use in any locality. There are 6 rows of steam pipes spaced so as to admit two trays between every two rows of pipes. The description of this drier is accompanied by figures showing the construction and working details.

Tunnel driers require more labour, and for this as well as other reasons they have never come into general use in the apple-drying districts of the eastern portion of the United States. They are suited for drying cherries, maize or other material best handled by spreading on trays.

The bulletin describes the preparation of fruit for evaporation, the evaporation of the fruit, the time required for drying, etc., and gives practical directions for drying peaches, pears, cherries, prunes, etc. The sun drying of fruits, the preparation of evaporated and dried fruits for market, are dealt with and the laws relating to evaporated and dried fruits in force in the United States are considered.

## 1406 - Review of Patents.

TILLAGE MACHINE AND IMPLEMENTS. — *Italy*: 159733 Universal plough with self regulator; 161069. VITALE motor balance-plough.

*New Zealand*: 39696-39825 Raising, lowering and depth regulating device for ploughs.

*Switzerland*: 79134 Soil tillage apparatus.

*United States*: 1273801-1274586-1274866 Harrows; 1273829 Attachment for ploughs; 1274075 Draft wheel connection for wheel and gang ploughs; 1274876 Stalk chopping machine; 1275209 Plough; 1275588-1276017 Cultivators; 1276051 Vineyard plough; 1276334 Combination plough and pulveriser; 1276645 Harrow tooth.

DRAINAGE AND IRRIGATION. — *Canada*: 184106 Excavator.

*Italy*: 160124 Self acting water lifter for drainage, irrigation, etc.

*Sweden*: 43482 Ditching machine.

MANURES AND MANURE DISTRIBUTORS. — *Italy*: 161557 Physiologically complete mineral manure of natural plant salts for directly fertilising all agricultural seeds and plants

*Sweden*: 43481 Manure spreader device.

*United Kingdom*: 117958 Combined manure and seed distributor; 118225 Machine for sowing seeds.

*United States*: 1274343 Fertilising method and material; 1275332 Fertiliser distributing mechanism; 1275683 Manure distributor; 1275736 Fertiliser chemical and composite distributor; 1276047 Feed regulator for fertiliser sowers.

DRILLS AND SEEDING MACHINES. — *Canada*: 184285 Land marker; 184533 Potato sowing machine.

*Sweden*: 43480 Potato planting machine.

*United Kingdom*: 117938 Potato planter; 117958 Combined manure and seed distributor; 118225 Machine for sowing seeds.

*United States*: 1274062 Three row maize planter; 1274239 Maize planter; 1274447-1274885 Planters; 1276588 Peanut planter; 1276646 Potato planter.

VARIOUS CULTURAL OPERATIONS. — *Italy*: 153315 PAVONE hoe; 160735 Tree straightener.

*Sweden*: 43483 Combined weeder and rake.

*United States*: 1274527 Mulch for sugar cane and the like; 1274718 Cotton chopper; 1275356 Maize cultivator.

CONTROL OF DISEASES AND PESTS OF PLANTS. — *Switzerland*: 79136 Motor sprayer; 79285 Rat trap.

*United States*: 1274201 Weed puller.

REAPERS, MOWERS AND OTHER HARVESTING MACHINES. — *Canada*: 184076 Flax harvester, 184532 Stooking mechanism; 184723 Grain binder mechanism.

*Sweden*: 43450 Mower device.

*Switzerland*: 79135 Basket attachment for mower.

*United Kingdom*: 118255 Fork for swath turning or potato digging machine.

*United States* : 1273814 Cotton harvester ; 1274432-1275551 Maize picking and husking machines ; 1275062 Cutter bar mechanism ; 1275599 Mowing machine ; 1275689 Platform latch for reapers ; 1276064 Transporting vehicle for grain shocks ; 1276295 Non clogging maize harvester knife ; 1276324 Maize cutter.

MACHINES FOR LIFTING ROOT CROPS. — *Sweden* : 43652-43683 Potato diggers.

*United Kingdom* : 117950 Machine for gathering, topping and cleaning root crops which have been dug either by hand or machine and laid in rows on the ground ; 118255 Fork for swath turning or potato digging machines.

*United States* : 1276441 Potato digger.

THRESHING AND WINNOWER MACHINES. — *Canada* : 184085 Potato separator.

*Netherlands* : 2554 Grain cleaning machine.

*Sweden* : 43391 Device for self cleaning thresher ; 43580 Threshing machine.

*United States* : 1274085 Potato sorter ; 1274881 Pea huller.

MACHINES AND IMPLEMENTS FOR THE PREPARATION AND STORAGE OF GRAIN FODDER, ETC. — *Canada* : 184070 Grain pickling device ; 184272 Bag holder.

*Sweden* : 43536-43685 Rack for drying grain and forage.

*United States* : 1273975 Hay cutter ; 1274180 Grain treating machine ; 1274541 Hay carrier ; 1274682 Baling press ; 1274849 Drier for seed maize ; 1275722 Hay loader ; 1276044 Cotton seed drier ; 1276190 Ensilage spreader and packer ; 1276205-1276295 Maize stalk rake ; 1276355 Cotton seed linter.

FORESTRY. — *Canada* : 184810 Tree sawing machine ; 184837 Rotary wood cutting machine.

*United Kingdom* : 117882 Cross cut saw for felling standing trees.

*United States* : 1276140 Stump burner.

STEERING AND TRACTION OF AGRICULTURAL MACHINERY. — *Canada* : 184163 Wagon tongue mechanism ; 184537 Traction belt.

*Sweden* : 43393 Driving wheel for motor plough and tractor.

*Switzerland* : 79133 Tractor for agricultural machine.

*United States* : 1274089 Draft equaliser ; 1274473 Mechanical tractor for agricultural purposes ; 1274574-1274968-1276035 Tractor attachments ; 1274588 Hydraulic motor ; 1275071 Extension steering device for tractors ; 1275343 Tractor frame ; 1275344 Track laying tractor ; 1275600 Tractor ; 1275761 Tractor hitch ; 1276515 Tractor wheel.

FEEDING AND HOUSING LIVESTOCK. — *Canada* : 184203 Animal releasing device ; 184499 Hog feeding machine.

*Italy* : 159905 Simultaneous releasing device for stables.

*United States* : 1274483 Horse shoe ; 1275144 Combination hog trough ; 1276449 Cattle stanchion.

POULTRY FARMING. — *United Kingdom* : 117890 Hand appliance for cutting up food for poultry.

*United States* : 1274104 Device to prevent hens from setting ; 1274166 Incubator ; 1276543 Incubator regulator.

FISHING. — *Canada* : 184451 Gill net sinker ; 184981 Fishing hook.

INDUSTRIES DEPENDING ON PLANT PRODUCTS. — *Canada* : 184191 Grain milling machine

*Italy* : 155198 New system of extracting sugar from sugar beet and other plants ; 159323 Apparatus for the rational germination of grains and cereals ; 159501 Citrus essence extractor with articulated combs working under water ; 159733 New wine-making process ; 159817 CARA oil and fermentation residue press ; 159915 Scutching machine ; 160033 Machine for the preparation, trituration, subdivision, multiple division and working of germinated wheat, or other cereal, vitalised, fermented or treated in any other way so as to soften it ; 160115 Worker for germinated cereals.

*Switzerland* : 79173 Bolting machine.

*United States* : 1273974 1274803 Nut cracking machines ; 1274704 Bread making machine.

DAIRYING. — *Canada* : 184277 Milk pail.

*New Zealand* : 39946 Milking machine pulsator ; 40103 Milking machine teat cup.

*Sweden* : 43317 Centrifugal separator driven by a petrol motor fixed underneath ; 43392 Separator drive mechanism ; 43427 Rotary churn with removable inside wing ; 43452 Device for vacuum milking machine ; 43577 Bowl device for rotary churn ; 43610 Device for heating milk before being fed into a separator driven by petrol motor.

*Switzerland* : 79332 Churn.

*United States* : 1273916 Cream separator ; 1274393 Combined churn and butterworker ; 1274748 Process of treating milk by heating to about 140°F. and cooling to about 40°F without removing from the same vessel ; 1274750 Process of treating milk and the like by sterilisation ; 1276184 Milking machine.

FARM BUILDINGS. — *Canada* : 184203 Animal releasing device.

*Italy* : 159905 Simultaneous releasing device for stables.

*United States* : 1274727 Horse shoeing stand ; 1275148 Silo ; 1276449 Cattle stanchion.

VARIOUS. — *Canada* : 184169-184701-184772 Pumps.

*Italy* : 160978 Improvements to rotary pump.

*United States* : 1273913 Centrifugal pump.

## AGRICULTURAL INDUSTRIES.

1407 — On De-foxing Wines. — RAVAZ, I., in *Le Progres agricole et viticole*, "Est-Centre" edition, Year XXXIX, No. 37, pp. 241-246. Villefranche, Rhone, September 15, 1918.

The author, looking back on the methods for de-foxing proposed in his journal (1), suggests that, in all these processes, oxidation probably plays the most important part. If this is so, on treating foxy or musky

(1) See R., May, 196, No. 555, Feb., 1917, No. 183 and June, 1918, No. 684. (Ed.)

musts or wines by an oxidising agent, the undesirable taste ought to be removed. Experiments made by the author have shown this to be the case.

There are many oxidising agents. The best results have been obtained with manganous acetate and potassium permanganate; but their use is not allowed in wine-making. Hydrogen peroxide, which adds nothing to the vintage that is not already present and leaves no trace behind, is still more active. At the strength of 10-11 volumes, used at the rate of 1 litre per hectolitre, in less than one hour all trace of a foxy or musky taste has been removed from the wine or must. The same result is obtained whether must or made wine be treated. If the dose is stronger, the action is also more rapid, but the oxidation is carried still further and wines are obtained that are aged by several months or even years.

In the grapes, musts and wines, there are natural oxidising agents. In particular there is a diastase which the author was the first to report in wine and which, especially in Grenache, greatly helps to turn an almost yellow shade and causes the bouquet to disappear. If sulphurous acid is used in winemaking, it should only be used after defoxing in order to limit the action of the diastase.

The same oxidase is produced in the grape by the fungus *Botrytis cinerea*, which causes grey mould.

Some day this oxidase may be obtainable commercially.

By making wine according to these directions a more or less marked "casse" will be produced in the wine, but its effects can always be controlled.

**1408—On a Water Bacterium Living in Bitter Wines that can Dehydrate Glycerine; Glycero-Reaction.** — VOISENET, E., in the *Annales de l'Institut Pasteur*, Vol. XXXII, No. 10, pp. 476-510. Paris, October, 1918.

The author has found the presence in water (1) of a ferment having properties similar to those of a bacterium living in bitter wines, which he had previously isolated and studied (2). Each of these organisms can dehydrate glycerine, changing it to acroleine. The author has studied these two bacteria, and has extended the work to cover other bacteria that may be found in water, such as *B. coli*, *B. typhus* and *B. para-typhus*.

The general morphological, biological, cultural and biochemical characters of the bacterium isolated from water, on comparison with those of the bacterium from bitter wine, show a close resemblance between the two organisms. Each organism, on inoculation into a suitable vinous medium, can produce the "bitter disease" of wine with all its organoleptic, microscopic and chemical properties, especially by forming, at the expense of the glycerine, acrylic aldehyde, a substance found by the author to be formed in all wines whether new or old, affected with true bitter disease.

Both organisms seem to belong to one and the same species which, from its habitat, its physiological function regarding glycerine and its pathological function in wine, the author has named *Bacillus amacrylus*, As the

(1) *Annales de l'Institut Pasteur*, Vol. XXVIII, p. 807, 1914. (Author.)

(2) See R., July, 1913, No. 871. (Ed.)

water bacterium constitutes the type species, that of bitter wine can be considered as the same species, with its hereditary qualities simply modified by the necessary adaption to its new food environment, or at any rate as a variety.

This work shows how the introduction of water into wine, which cannot be avoided in practice, whether during vinification or bottling, causes infection with the germ of the disease.

This water bacterium shows analogies and differences with *B. coli* and the typhus and paratyphus bacilli. Like them it grows in phenol broth at 1 % at 42° C. From its character as a lactic ferment, by its action on media coloured with litmus or neutral red, or colourless like the rosaniline medium of ENDO, it resembles ESCHERISCH's bacillus and differs from that of EBERTH and even the paratyphic one. The absence of indol-production would produce an inverse result in comparison, if it were not known that the types of colibacilli, of the variety *anindolicus*, can form that substance.

Two fundamental properties, the one biological, the other chemical, differentiate this organism from those compared with it by the author and which are, at any rate one of them of too common occurrence in water : — it is not pathogenic and it causes the acrylic fermentation of glycerine.

Using the property possessed by *B. amacrylus* of fermentating glycerine with the production of acrolein as a basis, the author describes a special reaction which he calls the "glycero-reaction", which enables this bacterium to be distinguished from the other above mentioned bacteria in water analysis.

1409 - Sudan Dura as a Brewing Material. — BRIANT, I. and HARMAN, H., in the *Journal of the Institute of Brewing*, Vol. XXIV (Vol. XV, New Series), No. 5, pp. 200-214. London, June, 1918.

In 1916 the Imperial Institute sent the authors samples of Sudan dura, with a request for their opinion as to its use for brewing purposes. The first experiments led the authors to conclude that, in spite of its high percentage of fat, dura might prove of value in brewing, especially in view of the present shortage of grain. In May, 1917, having obtained 5 to 6 tons of dura, the authors investigated the possibility of using it as 1) malt, 2) roasted grain, 3) flaked grain, 4) glucose, with the following results : —

MALT. — The dura is not easy to handle during germination; the acrospire, having no protective skin as in barley, is exposed and easily injured and detached during the frequent movement of the grain. Analyses showed a good development of enzymic activity as represented by the diastatic power (24° LINTNER as opposed to 30° for barley malt), and the results are similar to those for barley malt, except in the case of the extract, which is very scarce.

ROASTED GRAIN. — Experiments were made with malted and unmalted grain. The products were satisfactory in aroma and flavour and compared favourably with the products obtained from barley. The roasted grain was tested by London brewers for the manufacture of porter. The porter brewed with dura was better in colour than that brewed with roasted barley although a smaller proportion was used. Experts judged the flavour of the

first in no way inferior to that of the second. It was found possible to substitute dura for barley in the proportion of 7 of dura to 10 of barley without changing the character of the beer.

Two tests in the making of amber malt showed the flavour to be excellent, but the extract yield was low as a result of difficulty in malting. Could this difficulty be overcome it should prove possible to obtain a satisfactory extract.

**FLAKES.** — The flaking process is easily carried out and the starch gelatinises without difficulty. The yield in dura flakes was approximately 80 %, as compared with about 68 % for maize and 95 % for rice. Sufficient flakes were obtained to make comparative brewing tests in which half the usual proportion of flaked maize (15 %) was replaced by flaked dura. The results were satisfactory and brewing experts judged dura flakes to be equal to maize flakes. The author considers dura flakes perfectly suitable not only for brewing purposes, but also as a food for human consumption.

**GLUCOSE.** — Satisfactory preliminary results having been obtained, about 2 tons of dura were used for making glucose which was used in part for brewing. The sugar obtained was of the malto-dextrin type. The beers made were carefully examined. It was found that in new bitter beers decidedly better results were obtained with dura sugar than with invert sugar, but that in new mild ales dura sugar gave rather less fulness than invert sugar, but that in new mild ales dura sugar gave rather less fulness than invert sugar. The beers were again examined after 3 or 4 week's storage. The beers made with dura sugar were of better quality than those made with invert sugar.

The authors consider that if sufficient dura can be obtained at reasonable prices it may be used successfully as a substitute for roasted barley in the manufacture of flakes and sugar of the malto-dextrin type. Several tables of quantitative analyses are given.

**1410 — The Potato Starch Industry in Italy.** — GARELLI, F., in *Le Industrie Italiane Illustrate*, Year 1, No. 8, pp. 45-48. Milan, August, 1917.

The first potato starch factory was founded at Milan in 1885. This, facing great difficulties and owing to initial errors (foreign competition; insufficient protection of 2 lire per quintal; establishment in a large town distant from the large potato-producing centres; absence of sufficient experience in growing big yielding varieties) was obliged to suspend work. In 1900-1901, three starch factories were founded at Rovigo, Bologna and Ferrara, after the agricultural, and most important, side of the question had been thoroughly studied to assure success. After two seasons, the Bologna (the largest) works and that at Ferrara had to close down. At the end of the last century, a small works was installed at Polonghera (province of Turin) as the result of propaganda carried out by Prof. A. GARELLI of Turin University in favour of growing the industrial potato. As the district was unsuited to the industrial crop, the competition due to other better known and more paying crops led to its being abandoned.

It was owing to the success of the sugar-beet crop, that industrial potato growing was attempted in 1900-1901. Everything seemed favour-

able to the new industry, the cotton spinners alone imported 150'000 quintals of starch for finishing, of a value of 4 to 5 million *lire*; the sale price, including an import duty of 2 *lire*, varied between 30 and 32 *lires* \*the quintal. On the other hand the yield per hectare was 270 to 300 quintals for well prepared crops, thus assuring a satisfactory price of 3.5 to 4 *lire* per quintal.

The plant required for a starch factory is relatively simple; one-tenth of the capital required for a sugar factory suffices for a starch factory, which moreover, requires much less fuel.

A small works with 100 hectares of land available can work 200 to 300 quintals of potatoes per day for a season of 3 months, producing 50 to 60 quintals of starch per day or 5 000 to 6 000 quintals during the season. The Rovigo factory can deal with 500 quintals a day. From 15 to 20 starch factories, both large and small, and 3 000 hectares of land devoted to potato-growing would suffice for Italian needs. The Italian starch products are appreciated; and the reason for the failure of the industry to develop is especially foreign competition, the foreign product being sold at 23-24 *lires*, including the import duty. The starch factory could not reduce its prices without reducing the buying price of the potato. In 1911 there were 663 factories in Germany, including 441 agricultural starch factories.

According to the Bulletin of the Italian Ministry of Finance, the imports of European starch were: —

Years	Quintals imported	Average price in <i>lires</i> per quintal	Total value in <i>lires</i>
1909. . . . .	169 556	32	5 425 792
1910. . . . .	158 459	32	5 070 688
1911. . . . .	145 709	37	5 391 233
1912. . . . .	151 221	34	5 141 514
1913. . . . .	161 949	30	4 858 470

In these figures arrow-root and sago flours are not included. The starch from tropical plants is listed in the tariff as exotic starch; in 1913, 79 619 quintals of a value of 2 627 427 *lires* were imported. The total imports of starch thus represent a value of about 8 million *lires* annually.

At present only one starch factory — that at Rovigo — is working in Italy.

1411 — **War Syrups.** — DELLE, E., in *Le Moniteur Vicole*, Year LXIII, No. 41, p. 162. Paris, October 8, 1918.

It is absolutely prohibited to add saccharine to syrups (to the contrary of liqueurs, to which saccharine can be added freely) in France. As sugar is very scarce and glucose being both very scarce and very dear, syrup makers are very embarrassed. All that remains is honey and naturally-sweet fruits (figs, dates, etc.) which are only available in small quantities and that

at high prices. The makers have the alternative of preparing liquids without sugar, but of syrupy consistency, which they could not sell under the name of syrups, but which could replace them if the consumer himself would add a little saccharine to his drink.

To obtain the required syrupy consistency recourse may be had to plants containing mucilaginous matters of agreeable taste, or at any rate insipid and improved by adding suitable perfumes. Anything that might produce undesirable clots must, of course, be rejected. Gum arabic is excellent for this purpose, especially if good material is used; in fact some qualities give solutions which are clarified with difficulty, and any muddy syrup cannot be sold unless by its nature it is really opalescent.

On account of this year's fine grape harvest in France, the preparation of grape syrup is advised. It would be dear on account of the high price of wine, but it is an excellent product which, though long abandoned, is well worth reviving. It is made by heating vintage must, then skimming; chalk is added to neutralise the acidity somewhat; the liquid is filtered, and boiled vigorously until it weighs 32° Baumé. The product is kept in well-corked bottles in the dark in a dry place.

**1412 - Commercial and Domestic Fruit Drying.** — See No. 1404 of this *Review*.

**1413 - Opium Wax.** — JITENDRA NATH RAKSHIT, in *The Analyst*, Vol. XLIII, No. 510, pp. 321-322. London, September, 1918.

Wax is best extracted from opium by means of cold petroleum ether at the rate of 800 cc. of petroleum ether to 200 gm. of dry powdered opium. The ether is decanted off and the extraction repeated for 3 more days with 700, 600 and 500 cc. petroleum ether successively. The extracts are united, shaken with hydrochloric acid and then with anhydrous sodium carbonate. The solution is filtered and evaporated, giving 14.35 gm. of a brown, sticky mass having an odour somewhat resembling cod-liver oil. This opium wax gave the following results: — Iodine value, 152.5; Reichert value, 2.0; saponification value, 114.5.

**1414 - Acetic Acid Manufacture on Rubber Estates.** — KEUCHENIUS, P. E. (*Besockish Proefstation*), in *Archief voor de Rubbercultuur in Nederlandsche-Indië*, Vol. I, No. 5, p. 413-417 + 1 Fig. Batavia, 1917.

Owing to the continually increasing market prices of acetic acid, an attempt was made to produce acetic acid according to an old method and find out whether the acid obtained in this way would really be cheaper and whether rubber coagulated with this acid would be not inferior to rubber coagulated with imported acetic acid. Investigations by the Buitenzorg Central Rubber Station have proved that these questions are to be answered in the affirmative.

The method mentioned is very simple and is founded on the fermentation of alcohol to acetic acid. The whole installation required for this purpose consists of a wooden cask.

Taking into consideration the price paid now for alcohol, the acetic acid obtained through fermentation of alcohol will cost about 1s. 10d. per lb. Should it be possible to use methylated spirit, then the acetic acid would

cost about 3d. per lb. This acid, however, is of a low percentage concentration which can be easily ascertained by titration.

1415 - **Mechanical Coagulation of Rubber.** — ZUYDERHOFF, G. J., in *De Indische Mercur*, Vol. LXXI, No. 32, pp. 620-621. Amsterdam, 1918.

The author first reviews the best known methods for coagulating rubber, shows their respective advantages and disadvantages, and then describes the new method of coagulating by heat, together with the results it has given on testing it. The present high price of acetic acid and the hope of obtaining a product with better qualities lead the author to carry out the following experiments:—

The recipients usually used for coagulation are heated moderately from below while a current of ordinary or dry air is passed above. Another way consists in passing a current of warm air above the recipients containing the latex. To prevent the formation of a skin that would hinder the action of the air on the deeper layers of the latex, the author advises stirring the mass, or better still, keeping the recipients slightly agitated. The mass, when once well taken, is left and finally crêped. The colour of the crêpe thus obtained is quite light although in the first tests it varied greatly in each sample. The quality of the product seems quite comparable with that of samples obtained by chemical coagulation. The author insists on the economic side of the method, which, by this fact alone, is of interest and worth perfecting through further researches.

1416 - **The Utilisation of Coal Dust for Heating Greenhouses.** — RIVOIRE, P., in the *Revue Horticole*, Year XC, No. 9, pp. 157-158. Paris, September 16, 1918.

In order to utilise coal dust, M. REVERCHON, horticulturist of Moulin-à-vent, near Lyons, France, devised a method of consolidating it with lime, as tar cannot be obtained at present. He made bricks, using an iron mould such as that used by masons for making flag-stones. The mould is composed of two flat, elbowed irons, joined at the edges by clamps. The mould is placed on a piece of sheet iron with two handles, which enables it to be carried. The bricks are made with 5 kg. of lime, 20 litres of water and 100 kg. of coal.

The lump quicklime (now sold at Lyons at 11s. 10d. per hectolitre weighing 158 to 165 lb.) must be slacked one or two days before use with an equal quantity of water. When making the bricks the lime is put in a wooden tub together with the required amount of water and mixed vigorously with a trowel. The coal is placed on the ground near at hand. A hole is made in 100 lb. of the dust and the contents of the lime poured into it in two or three times. The mixture is stirred with a shovel to mix it well and distribute the moisture equally. The mould is then filled with the mixture by means of a trowel and the contents pressed down. The slight hollow formed is filled up, the whole re-pressed, and levelled with a trowel. The bricks are taken from the mould by removing the clamps and dried in the shade for about a week. If they are dried too rapidly in the sun the mixture remains powdery and the bricks break up too easily. The bricks weigh 11 to 13 lb., so that 100 lb. of coal will make 9 bricks. With a little practice 22 bricks an hour may be made.

To test the use of the bricks a fire was lit in a greenhouse furnace. Although little wood was used the bricks took fire easily. They ignited gradually and gave out a great heat although they were made with very bad coal. It is difficult to understand the part played by the lime, though it seems to act as a cement.

In view of the shortage of fuel this method is very valuable. It would also be of great service to horticulturists by allowing them to use dust of bad quality coal for heating their greenhouses.

1417 - **The Refractometric Estimation of Milk Sugar.** — PANCHEAUD, L. and AUERBACH, E. (Cantonal Laboratory, Geneva), in *Travaux de Chimie alimentaire et d'Hygiène*, Vol. IX, Pt. 5, pp. 236-239 + 3 Tables. Berne, 1918.

INDUSTRIES  
DEPENDING  
ON ANIMAL  
PRODUCTS

Communication to the 30th General Meeting (1918) of the Swiss Society of Chemists and Analysts.

The refractometric estimation of the lactose in cow's milk, started by WOLLNY (who used a calcium chloride serum and a special milk refractometer) has made little progress. But ACKERMANN, using his chlorocalcic serum and the ZEISS immersion refractometer, has shown that WOLLNY's tables could, with some slight modifications, be adapted to the graduation of the immersion refractometer (*Mitteil. Lebensmitteluntersuchung und Hygiene*, Vol. VII, p. 319. Berne, 1916). GABATHULER has drawn attention to the importance and value of lactose for valuing milk from a hygienic standpoint; in fact a clear decrease in the lactose is seen in sick animals, especially if they are suffering from diseases of the udder (*Zeitschrift für Fleisch und Milchhygiene*, 1915, Vol. XXV, p. 97). Since then the method has become very interesting. In order to ascertain the final difference between the lactose content estimated refractometrically and that obtained gravimetrically, the authors have tested a large number of milks of different origin and varying freshness (normal or watered fresh milks, sour milks, abnormal milks from sick cows) by means of the ACKERMANN method for the refractometric estimation and the ALLHYN method for the gravimetric estimation. The results, given in table form, lead to the following conclusions: —

1) *For fresh, normal or watered milks*, there is a remarkable concordance between the refractometric and gravimetric results.

2) *For sour milks*, the refractometric method gives results that are too high (one part of lactose, changed into lactic acid of a high refractive power, and one part of albuminoids coming into solution, are no longer precipitated by the calcium chloride).

3) *For abnormal milk from sick animals*, the refractometer figure is too high, owing to the increase in the chlorides and changes in the albumins and casein due to the pathological condition.

1418 - **Free Lactic Acid in Sour Milk (1).** — VAN SLYKE, L. L. and BAKER, J. C. (Chemical Laboratory of the New York Agricultural Experiment Station, Geneva), in *The Journal of Biological Chemistry*, Vol. XXXV, No. 1, pp. 147-178 + 12 Tables. Baltimore, July, 1918.

When speaking of the acid constituents of sour milk, the lactic acid is understood, as if the acidity were due directly and entirely to the presence

(1) See the summary of a previous paper by these writers, in *R. May*, 1918, No. 576. (*Ed.*)

of free lactic acid as such. When milk sours under ordinary conditions, lactic acid is first formed, but this reacts at once, practically as fast as formed, with the basic constituents present in the milk. In fresh cow's milk, the compounds reacting with acids are, first, basic phosphates and citrates of calcium, magnesium, sodium and potassium, and, second, calcium caseinate. When the lactic acid of sour milk reacts with these compounds numerous salts are formed, the essential results of the reactions being monocalcium phosphate, free casein and calcium lactate. In view of this there will not be much free lactic acid in souring milk until these reactions are practically completed.

The authors have used three methods for determining the amount of lactic acid in sour milk: — 1) measurement of hydrogen ion concentration and application of the mass law; 2) double electrometric titration with lactic acid and hydrochloric acid; 3) partial extraction by ether; the technique of each of these methods is described in detail. They further carried out experiments on the influence of the adsorption of lactic acid by the casein and studied the effect of certain factors on the free lactic acid content and on the coagulation point of the casein in sour milk.

RESULTS. — 1) In sour milk most of the lactic acid is present as lactate. Part of the free acid is in solution while a smaller part is adsorbed by the casein. A Freshly separated skim-milk, pasteurised at 62°C., cooled to 25°C., and inoculated with *Bacterium lactis acidii* showed no appreciable quantities of free lactic acid until 20 hours after inoculation (there were then 0.1 cc of acid in 0.1/N solution in 100 cc. of milk; this amount then increases fairly rapidly, amounting to 20 cc. after 48 hours)

2) In milk soured at 25° C after undergoing various treatments (pasteurised milk inoculated with *B. lactis acidii* or *Bacillus bulgaricus* or *Streptococcus lacticus*; inoculated unpasteurised milk; etc.) the total acidity varies from 70.5 to 220 cc. of 0.1/N acid per 100 cc. of milk; the free lactic acid from 8.6 to 124 cc.; the acid as lactate from 51.8 to 92 cc.; the hydrogen-ion concentration from 3.70 to 4.56. In milk soured under ordinary conditions, the total acidity varies from 70.5 to 107.5 cc.; the free lactic acid from 13.1 to 34.5 cc.; the hydrogen-ion concentration from 4.02 to 4.43.

3) About 20 % of the free lactic acid is absorbed by the casein in coagulated sour milk and the milk casein begins to coagulate when the hydrogen-ion concentration reaches 4.64 to 4.78. The time from beginning to end of coagulation varies from 30 to 60 minutes, during which time the hydrogen-ion concentration remains constant.

4) The first physically and easily perceptible sign of souring in milk is a characteristic smell and taste, due to the presence of some volatile compound formed in the souring process and not to lactic acid.

There is no apparent relation between either the hydrogen ion concentration or the acidity by titration and the first sign of this flavour.

1419 — "Renovated" Butter. — *Revue Scientifique*, Year LVI, No. 16, p. 504. Paris August 17-24, 1918.

Whilst increasing the quantity of food stuffs they produce the United States are also attempting to improve the quality and increase the

commercial value. M. G. D'AVENEL gives a significant example of this. Instead of heavily salting their summer butter, the amount of which exceeds the demand, and which is usually mediocre butter not easy to sell, the American farmer has devised what was first called "magic butter", then "boiled" or "sterilised" butter, and which is now known officially as "renovated butter".

The butter is melted as soon as bought on the market by the 80 firms that use the method, then solidified in iced water after 1 % of glycerine and 5 % of salt have been added, then preserved in closed recipients until winter. To return it, according to the demand, to its original state, the salt and glycerine are carefully extracted by again melting it; it is mixed with 3 times its volume of milk, and the emulsion of butter and milk obtained in this way exactly resembles fresh cream, which is then churned in the usual way. "Renovated butter" is quite pure, since it contains no foreign matter, and, although it is required by law to be labeled "renovated butter", it is nevertheless much in demand on account of its price, more modest than that of choice varieties.

**1420 - The Manufacture of Casein from Buttermilk or Skin Milk.** — DAHLBERG, A. O., in the *United States Department of Agriculture Bulletin* No. 661, pp. 32 + 9 Figs. + 6 Tables. Washington, April 9, 1918.

The utilisation of by-products by a large number of creameries is daily becoming of more economic importance. Because of the ever-increasing competition, the future success of many creameries depends in no small degree upon both the quality of their products and the extent to which by-products may be profitably utilised.

In the past skim-milk casein is the only kind that has been made in large quantities; a good grade of casein can also be profitably made from buttermilk, when it does not bring exceptional prices for food. It is advisable to convert the buttermilk into food products when proper markets can be obtained, as greater profits can then be obtained. But as it is not always possible to utilise all the buttermilk in this way, it is important to be able to turn the surplus into casein, which keeps perfectly and finds a ready market.

**BUTTERMILK CASEIN.** — The recovery of casein from buttermilk by the method to be outlined depends on the normal acidity of the buttermilk. The sour buttermilk from the churn, or that which has ripened to the required acidity, is heated sufficiently to cause a rapid separation of the curd and whey. Owing to the fineness of buttermilk curd every precaution must be taken to prevent it from being broken up any finer, which makes handling more difficult. Turning steam directly into the butter tends to break the curd up. The method devised for suitably heating the buttermilk is to run it through a steam jet or ejector, which gives the desired temperature in a rapid and efficient manner and with very little agitation of the curd. With buttermilk of sufficient acidity a good separation should be obtained at a temperature varying between 115° and 130° F (46.11° and 54.44° C). This method is based on results obtained in devising a method for handling

surplus buttermilk at the Grove City Creamery, Pa., operated under the supervision of the Dairy Division, U. S. Dept. of Agriculture. The method has been thoroughly tried in a commercial creamery, where it is giving most satisfactory results.

*Precipitating the curd.* The buttermilk from the churn is pumped into a tank elevated sufficiently to allow it to run by gravity through an ejector and from there into another tank below, whose gate valve is high enough to let the drain rack run under it. To save time, the heating should be done quickly. A valve placed in the buttermilk pipe leading from the tank to the ejector, and one in the steam pipe next to the ejector, permit easy control of the temperature to which the buttermilk must be heated to obtain proper separation. While conclusive data bearing on the acidity required for the most favourable results have not been obtained, an acidity of from 0.65 to 0.80% at the time of precipitation apparently gives the best working conditions. Buttermilk kept too long and highly acid tends to give a soft, sticky curd difficult to handle, especially when a high precipitating temperature is used. By varying the temperature used the proper degree of heat necessary to get good results may be obtained. At that temperature the buttermilk coming from the ejector is in such a condition that the curd rises quickly to the top, leaving the clear whey below. As soon as the curd has massed at the surface, which requires only a few minutes, the greater portion of the whey can be drawn from the bottom of the vat into the cloth-lined drain rack. The clear whey passes through the drain cloth quickly and by gradually closing the gate valve as the curd lowers in the vat, nearly all of it can be drained away. When the whey has drained away, the hot curd is placed on the drain racks ready for washing. The curd is washed at least twice with cold water, using a shower-bath spray nozzle. The drainage water should test less than 0.20% acidity, which is possible with two washings. The curd is placed in a form made of 1 inch surfaced material 20 in. square and 8 in. deep which is lined with 2 press cloths; the cloths are turned over from both sides so as to hold the curd securely when pressure is applied. The curd is pressed heavily until the curd is sufficiently dry for satisfactory grinding. The dry curd is ground finely, then dried. Fine-mesh screening must be used for the drying trays, as the buttermilk casein is very fine, not flaky like that made from skim milk by the addition of commercial acid. The curd is then spread uniformly over the drying trays by means of a simple shaker screen, like those used for screening sand.

The time required for proper drying depends on the condition of the curd, the uniformity of the spreading on the trays, and the volume and temperature of the air passing over the curd. The volume and speed of the air blowing over the curd should not be excessive, but sufficient to carry off the moisture readily. If the air current is too swift the dried casein is blown off the trays. A temperature of 130° F (54.44°C) is sufficiently high for all purposes. Casein dried at that temperature comes from the drier in a fine-grained condition and breaks up easily, while that dried at a higher temperature tends more to cake in one mass and is harder to grind to the same

degree of fineness. High temperatures may give casein that is more difficult to dissolve or discoloured. The casein can be dried completely at 103° F., provided that the curd has been properly ground and spread upon the trays in the proper manner.

The best type of drier is made of tongue-and-groove boards nailed both sides of the studding, the space between being filled with insulating material. The tunnels should be lined with galvanised iron if they are to be used continuously as the hot air dries the boards out. The double tunnel drier is the most economical. The tunnel should be 1 inch wider than the trucks and drying trays. Many tunnels are made 31 or 32 inches wide to take the 30 in. square drying trays that can be bought ready made. The tunnels used in these experiments were 24 in. wide. A double-tunnel drier, 22 ft. long, 5 ft. high, and each tunnel 24 in. wide will hold trays filled with the casein from 20 000 lb. of buttermilk. The driers can be made of any length and height but should be high enough to allow a man to walk in and out easily when pushing the trays.

A blower of sufficient capacity to send a large volume of heated air over the ground curd is required. Details are given for the construction of the drying trays and trucks, the curd mill, the curd press, the drain rack (like those used in the manufacture of cottage cheese) and other accessories.

It is advisable to grind and screen the casein after it comes from the drying tunnel in order that it may be of uniform grain and appearance; after it is shipped in strong sacks.

On the average 100 lb. of undiluted buttermilk yield on the average from 2.8 to 3.1 lb. of dried casein. In many creameries the cream is diluted with too large a quantity of water before churning, thus giving lower yield of casein.

No definite figures can be given on the cost of manufacturing, as cost-accounting data were not kept that could give results applicable to ordinary creamery conditions. If 10 000 lb. of more of buttermilk are handled daily the cost of making dried casein should not exceed 3 cents per lb. in the U. S.

The factors that have an important influence upon the quality of the buttermilk casein are:—the fat content of buttermilk; washing the precipitated curd; temperature of drying the ground curd; temperature of precipitating the curd; acidity of buttermilk at the time of precipitation. These factors are considered separately. Since the fat originally in the buttermilk is concentrated in the dried casein, it probably has a deleterious effect upon the strength and general working properties of the casein. An increased quantity of fat yields a casein of poorer solubility and strength. The effects of these various factors are shown in a number of tables.

**SKIM-MILK CASEIN.** — This is usually made by adding crude commercial sulphuric acid to the fresh skim milk after heating the latter to a temperature of 120° F. (48.8° C.). The advantage of this method is that the skim milk can be disposed of quickly and at a time when the quality of the curd is in the best condition.

The skim-milk is heated directly by steam in a wooden vat to 120° F., never above 125° F. Commercial sulphuric acid (1.83 specific gravity)

is then added at the rate of one pint to every 1 000 lb. of milk, at the same time stirring the mixture continuously. Before using, each pint of acid should be diluted with about a gallon of water. After adding the acid the skim-milk is stirred gently until the curd is well separated, which takes only a few minutes. If the curd does not separate well more acid may be added. The clear whey is run off and the curd remaining in the vat is rinsed with cold water to remove the excess of whey and acid remaining. The curd is then placed in the burlap or duck press cloths and put to press till sufficiently dry. The curd is then ground, placed on the trays and dried in the tunnel drier.

The cooked-curd method of making skim-milk casein, requiring practically no equipment save the precipitating vat, is coming into general use among creameries near to a central drying plant. The skim-milk is heated to 120° F. and sulphuric acid added to coagulate the casein, as described above. After draining off the whey the curd is broken up in the vat, covered with water, and the mixture heated to 170°-175° F. (76.67° to 79.44°C.) by means of direct steam. At that temperature all the curd should collect in a semifluid, plastic, tough mass. The water is drained off and the soft curd placed in a barrel, where it settles into an almost air-tight mass which on cooling changes to a very tough impervious mass that will keep for several days, even in hot weather. The barrels filled with cooked curd and covered with burlap can be shipped to the central drying plant. Cooked curd is hard to grind and requires an especially strong mill.

Casein can be made successfully from skim milk with the ejector method of precipitating the curd, but care must be taken in allowing the skim milk to curdle before heating, or a tough, rubbery curd, impossible to handle, will result. The curd from naturally soured skim milk, separated by the ejector method of heating, is not only handled as easily as that precipitated with sulphuric acid but is not nearly so tough nor so hard to grind.

From 100 pounds of average skim-milk between 3 to 3.25 lb. of casein can be obtained.

After describing the requirements for good casein (especially its solubility, adhesiveness, and general working qualities), the author considers the casein markets and prices.

A few years ago casein cost from 5 to 7 cents a pound, but during the last 2 years the price has doubled or more; at one time even 22 cents a pound was offered in the United States.

1421 - **The Installation and Equipment of an Egg-Breaking Plant.** — JENKINS, M. K., in the *U. S. Department of Agriculture, Bulletin No. 663*, 25 pp. + 25 Figs. + 2 Photographs + 2 Tables + Bibliography of 5 Publications. Washington, May 27, 1918.

The aim of this bulletin is to assist manufacturers of preserved liquid eggs to make a judicious choice of apparatus and to instal their plant so as to prepare the preserves hygienically and, at the same time, assure the maximum economy of space and labour. A modern plant of this kind must contain a chilling room for whole eggs, a candling room, a chilled room for breaking the eggs and removing the contents from the shell, a room for wash-

ing and sterilising the utensils used for breaking and separating, and a refrigerating room for the rapid freezing of the liquid eggs and their storage.

A plan shows the arrangement of the different rooms. It provides for a staff of 12 breakers and a daily output of 120 cases if the white and the yolk are separated and of 180 cases if the eggs are preserved whole. A skilled worker may prepare 12 to 15 cases of whole eggs daily and 8 to 10 cases if the white is separated from the yolk. The temperature of the rooms varies according to the purpose for which they are used. The temperature of the chilling room should be from 32 to 40°F., that of the candling room from 50 to 55°, of the breaking room from 60 to 65°, the sterilising room normal and that of the refrigerating room from 0 to 10°F. All the rooms should be suitably insulated. The breaking and sterilisation rooms should receive plenty of natural light from windows. The walls and ceilings of these two rooms should be plastered and white enamelled and the floors concrete with trapped drains. Between the two rooms should be a sliding window for the transfer of equipment. The refrigerating room should be equipped with shelves of piping through which passes the brine for freezing the cans of liquid eggs. The shelves should be 20 in. wide and about 15 in. apart.

The candled eggs are removed to the breaking room in metal pails. Leaking eggs after candling are placed in special square trays (made of galvanised iron with an iron plate perforated to hold 36 eggs; it is 12  $\frac{1}{4}$  in. square and 3  $\frac{1}{2}$  in. high) for removal to the breaking room. The apparatus used in the liquid egg preserving industry must, like that of dairies, be made of material which washes easily and does not rust.

The eggs are broken into glass cups which make it easy to see which eggs should be rejected. The cups should be of thick glass capable of holding two eggs but not more; sometimes only one egg is broken into each cup. The cups are placed on a special metal tray fitted with a detachable knife on which the eggs are broken. The knife rests in slots in standards fastened to the ends of the tray. When the white is separated from the yolk this should be done by a sanitary mechanical device. The tables should be covered with non-absorbing material, such as metal or porcelain. A full list of the requisite apparatus is given in a table; part of it may be bought ready made, but part must be made to order.

Before freezing liquid eggs the whites and the yolks must be mixed in a special churn fitted with a motor-driven paddle. This is one of the most important pieces of apparatus in the breaking room. Two types of churn are at present in use, one chills the eggs to nearly freezing during the churning process, the other simply mixes the eggs. The first type is indispensable in establishments having no adequate refrigeration system for cooling the eggs before breaking and rapidly freezing the liquid eggs. Holding the eggs at a warm temperature, even for a few hours only, causes a rapid multiplication of bacteria. The refrigerating churn most commonly used is a modified pasteurising machine which may be bought from dairy supply firms. Non-refrigerating churns are also described and illustrated by figures. It is essential that the churn be made so that it may be rapidly washed and sterilised. The sterilising room must contain sinks for washing the utensils.

and sterilisers. The sinks must be fitted with mechanical rinsers and drains.

Frozen liquid eggs are usually sold in 30 lb. tins, but sometimes in 20, 10 or 5 lb. tins, especially in the case of the whites of eggs.

1422 - **Microorganisms and Heat Production in Silage Fermentation** (1). — HUNTER, O. W. (Dairy Bacteriologist, Kansas Agricultural Experiment Station), in the *Journal of Agricultural Research*, Vol. X, No. 2, pp. 75-83 + 10 Figs. + Bibliography of 15 Publications. Washington, July 9, 1917.

Different workers disagree as to the cause of heat production in silage. Some consider it to be due to respiration of the tissue cells, others to respiration of tissue cells and microorganisms and others to microorganisms alone. In order to solve this problem the author ensiled maize, alfalfa, sugar cane and kafir under the following conditions: — 1) normal, natural fermenting forage; 2) forage treated with antiseptic; 3) forage treated with heat; 4) forage treated with heat and inoculated with bacteria; 5) dried forage.

Heat production occurred in the untreated and inoculated forage; in the other cases the rise in temperature was due to heat absorption. Dried forage undergoes normal fermentation when water is added. Heat production in silage is, therefore, due to bacterial activity and not to respiration of the tissue cells.

1423 - **The Cork Industry**. — BARRIS, in *Le Chêne-Liège*, Year XXIV, No. 635. Bone (Algeria), September 15, 1918.

Report by the author, Financial Delegate on the Committee of the Councillors for Foreign Trade at the French Ministry of Commerce and the General Government of Algeria, dealing with the general question of Algerian and French corks and its relation to other countries.

**WORLD'S CORK PRODUCTION.** — Cork production is strictly limited to the Western Basin of the Mediterranean and the Atlantic coasts of the Iberian Peninsula and South-West France. Expensive attempts have been made to plant the cork-oak in many places (California, Australia, the Cape, Japan, etc.), but with wholly negative results. Countries having forests of this tree thus enjoy a natural monopoly.

The appended Table shows that Algeria alone furnishes nearly  $\frac{1}{3}$  of the world's production; France, Algeria and Tunis together furnish just over  $\frac{2}{5}$  of that production, without including Morocco, where there are vast forests that will soon be exploited. The cork industry is very little developed in France and it practically does not exist in Algeria.

**WORLD'S CORK MARKETS.** — The greatest consumers of unworked cork, not including France, are: — England, Russia, Germany, Austria-Hungary and the United States. The four last-named countries admit unworked or slab cork duty free and subject worked cork to heavy duties to protect the home industries. England is the only one of these nations that admits both raw and worked cork duty free, but the cork comes mostly from Portugal and Spain.

(1) See also R. July, 1917, No. 650. (Ed.)

*Area and yield of cork-oak forests.*

	Area of cork-oak forests hectares	Yield in cork of these forests quintals
France . . . . .	150 000	120 000
Algeria . . . . .	426 000	419 000
Tunis . . . . .	82 000	50 000
Italy . . . . .	80 000	40 000
Spain . . . . .	250 000	275 000
Portugal . . . . .	300 000	425 000
Morocco . . . . .	note	note
<i>Totals . . .</i>	<b>1 288 000</b>	<b>1 329 000</b>

UNWORKED CORK. — The following countries imported the following amounts (in quintals) of raw cork in 1913: — France, 66 000; Russia, 72 000; Germany, 58 000; Austria-Hungary, 56 000; Belgium, 35 000; Netherlands, 22 000; United States, 55 000; Spain, 30 000; England, 9000; Sweden, 4000; Denmark, 4000; Italy, 2000; Japan, 2000.

The exports of raw slab cork from Algeria into France are sent for to be partly turned into worked products. France re-exports part of the Algerian cork as well as part of the home product in the raw state, while she has to import worked cork, which shows the inferiority of her bottle-stopper industry, although France is the most important market in the world for the worked products, on account of the large amount of wine bottling carried on.

The countries of central Europe, Belgium, the Netherlands and the United States appear to have taken the first place on the Algerian cork market.

The exports of male cork, debris, etc. preponderate in this trade. The exports to Central Europe and America mostly consist of these products, used for making cork powder, agglomerates, now so much used, and linoleum.

On considering market cork only, it is seen that the above-mentioned countries hold a good place, but it will be found that France and Russia absorb  $\frac{2}{3}$  of the good Algerian cork, while the great mass of the by-products and inferior qualities is taken by the Austro-German and American trade which transforms it, reexporting a part after manufacture.

WORKED CORK. — The Algerian exports of worked cork are so far very limited. In 1913 they reached 6500 quintals, and represent the product of about 10 000 quintals of raw cork. About 70 % of these exports goes to France, while the rest goes to Central Europe, especially Austria-Hungary, whose importations through Adriatic ports are gradually increasing.

THE ALGERIAN INDUSTRY. — This is quite rudimentary, only working 10 000 quintals in the best year (1913).

There was a double reason before the war for this state of affairs. On the one hand, the local consumption is small and will only increase

slowly in the future. On the other hand the big cork-consuming and non-producing countries have taken measures to assure that the cork will be transformed into worked products in the importing country by placing light duties on unworked cork and very heavy, if not prohibitive, duties on worked cork (save Great Britain).

The author points out the necessity for France to obtain, after the war, free trade between all countries for worked cork or, at any rate, equality as regards import duties for all corks in all countries.

## PLANT DISEASES

### DISEASES DUE TO FUNGI, BACTERIA AND OTHER LOWER PLANTS.

1424 - **New and Rare British Fungi.** — WAKEFIELD, E.M., in the *Royal Botanic Gardens, Kew, Bulletin of Miscellaneous Information*, No. 7, pp. 229-233. London, 1918.

GENERAL

Among the seven species of fungi observed in Great Britain from 1916 to 1918 and recognised as new to science or to the mycological flora of the country, the following deserve special mention: —

1) *Merulius Pinastri* Burt., found in abundance at the Botanical Gardens at Kew in September, 1917; the conditions in the greenhouses are so favourable to its development that at times it becomes almost a pest.

2) *Nectria fusco-purpurea* n. sp., observed at Wisbech in 1917 on dead branches of Pond's Seedling plum trees; there is no evidence that this fungus caused the death of the branches, but it was not found on any other variety of plum.

3) *Cercospora Antirrhini* n. sp., reported from Worcester (September, 1917) and from Birmingham (June, 1918) as damaging *Antirrhinum*, the leaves and stems of which it attacked.

4) *Mastigosporium album* var. *muticum* Sacc., on leaves of *Dactylis glomerata* at Oxshott (October, 1917) and at Kew (1918).

5) *Helminthosporium Warpuriae* n. sp., on an injured stem of *Warpuria clandestina* at Kew in July, 1917; this fungus appears to belong to the class of facultative parasites, having entered the plant through a wound; it grew there parasitically, but probably as a rule it is a saprophyte and would not attack an uninjured plant.

1425 - **Patents for the Control of Diseases and Pests of Plants.** — See No. 1406 of this Review.

MEANS  
OF PREVENTION  
AND CONTROL  
DISEASES  
OF VARIOUS  
CROPS

1426 - **Diseases Reported on Wheat in Java.** — PALM, B., in the *Mededeelingen van het Laboratorium voor Plantenziekten*, No. 34, pp. 1-21 + 12 Figs. + 1 Plate. Batavia, 1918.

In 1918 the Department of Agriculture, Industry and Commerce conducted wheat growing tests in the high and low regions of Java. In the high regions, the results were, as a rule, satisfactory, save for the fact that a more or less large number of wheat plants of different varieties (the tests had been carried out with wheat varieties from Europe and India) was attacked by fungous diseases amongst which *Ustilago Triticici* (Pers.) Rostr. and *Gibberella Saubinetii* (Dur. and Mont.) Sacc. = *Fusarium rostratum* Appel and Wollenw. are of considerable importance. The diseases were probably introduced with wheat grains as they were previously unknown in

[1424-1426]

Java. Since then, *Helminthosporium gramineum* (Rab.) Eriks. (?), *H. geniculatum* Tracy and Earle, and *Nigrospora Panici* Zimm. have been recorded as injurious. The author is as yet unable to say whether the two *Helminthosporium* diseases originated in Java; he is, however, of that opinion, as he has occasionally found both the species on maize. *Nigrospora Panici* has been long known in Java.

1427 - *Uromyces pedicellatus* n. sp., a Rust Injurious to *Eragrostis abessinica* and *E. curvula* in the Transvaal. — POLE EVANS, I. B., in the *Royal Botanic Gardens, Kew, Bulletin of Miscellaneous Information*, No. 7, pp. 228-229 + 1 Fig. London, 1918.

According to observations made by the author at Pretoria, Transvaal, the stems and leaves of *Eragrostis abessinica* Link. (= *Poa abyssinica* Jacq.), locally known as "teff", are very seriously attacked in South Africa by an *Uromyces* which does not appear to have been described hitherto. The leaves and stems of *E. curvula* Nees are also frequently attacked by an *Uromyces* differing slightly from *U. Eragrostidis* Tracy, already described on *E. pectinacea* Nees in North America and on *E. cynosuroides* Beauv. in India. The *Uromyces* on *E. curvula* is identical with that on *E. abessinica* and it seems not improbable that the rust which attacks *E. abessinica* in South Africa has passed on to it from *E. curvula*. The author describes this rust under the name of *U. pedicellatus*.

1428 - *Cronartium occidentale* n. sp., a Rust Injurious to *Pinus edulis*, *P. monophylla*, *Ribes* spp. and *Grossularia* spp. in Colorado and Arizona, U. S. A., — HEDGECOCK, G. G., BETHEL, E. and HUNT, N. R., in the *Journal of Agricultural Research*, Vol. XIV, No. 10, pp. 411-424 + 1 Fig. + 1 Plate. Washington, December 2, 1918.

The authors describe as a species new to science *Cronartium occidentale*, a parasite of *Ribes* spp. and *Grossularia* spp. This rust has been observed in Colorado for many years and also in Arizona and seems to have been found in Kansas on *R. aureum* before being reported from the other two States. By means of cultures it has recently been found possible to grow it on *Ribes* spp. and *Grossularia* spp. even in the Columbia district (Washington).

Repeated inoculation experiments have shown the aecidial stage of this fungus to be represented by a species of *Peridermium*, at present known as *Per. occidentale*, which has so far been found on 42 *Pinus edulis* trees in five different districts of Colorado and on one *P. monophylla* near Prescott, Arizona. These two pines, together with *P. combroides*, which is probably also a host of *Per. occidentale*, and *P. quadrifolia*, are known as "pifion" pines. As this rust has only been observed on the trunks and branches of pifions and, so far as is known, does not attack other pines, it has been called pifion blister rust. In the various districts of Colorado and Arizona in which *Cron. occidentale* has so far been observed the common host of the urediniospores and teliospores is *R. aureum*, although both these forms are sometimes found on *R. odoratum*, *R. inebrians*, *Grossularia reclinata* × *Gr. hirtella* and *Gr. leptantha*.

*Cron. occidentale* was inoculated with positive results into *R. americana*

*num*, *R. aureum*, *R. coloradense*, *R. Giraldi*, *G. glandulosum*, *R. malvaceum*, *R. nigrum*, *R. odoratum*, *R. sanguineum*, *Ribes* sp., *Gr. inermis*, *Gr. missouriensis* and *Gr. reclinata*  $\times$  *Gr. hirtella*.

*Cron. occidentale*, which differs from *Cron. ribicola* in the aecidial stage especially, seems capable of over-wintering on *R. aureum* and remaining independent of the aecidial stage.

*Per. occidentale* is rarely found, at a certain distance above the soil, on very old *P. edulis* trees, and occurs in the crevices of the bark, often without adjacent dead areas. In such case the fungus is hardly discernible, even with a hand lens. Its effects are clearer on young trees, a number of which, apparently killed by the fungus, have been found in South Colorado. They are usually attacked on the trunk and branches near the soil, some becoming spike-topped. Plants of *Ribes* and *Grossularia* attacked by *Cron. occidentale* seem to suffer but slight injury. If the attack is severe partial loss of leaves will result, and repeated attacks may cause stunted growth, but no trees killed by this fungus have been found.

## WEEDS AND PARASITIC FLOWERING PLANTS.

1429 - **Orchid Parasitic on the Leguminous Plant *Caesalpinia coriaria*, in the Dominican Republic.** — See No. 1363 of this *Review*.

1430 - ***Sorghum halepense*, a Weed in Porto Rico.** — STEVENSON, J. A., in the *Revista de Agricultura de Puerto Rico*, Vol. I, No. 3, pp. 132-135 + 2 Figs. San Juan, Porto Rico, 1918.

The presence of *Sorghum halepense* (Johnson grass, "yerba de don Carlos" or "canuela") is reported from Porto Rico. The grass has been noted in various places in the neighbourhood of Rio Pedras and is fairly common in the pineapple-growing zone near Vega Baja; it is certainly present in other parts of the island. The weed has begun to spread largely in the pineapple plantations, causing considerable damage.

As regards means for controlling the grass, the first precaution is to avoid bringing it into the fields as a forage crop, because the disadvantages resulting from its great tendency to spread and the difficulty with which it is extirpated once it has taken root are much greater than its value as food for cattle.

If the plant has already spread in a field radical measures must be taken at once; and seed formation must be avoided at all costs. It must be removed by tearing up its rhizomes; after a few weeks the operation should be repeated to destroy the plants produced by the pieces of rhizome remaining after the first removal.

When the plant has already taken possession of a considerable area the rhizomes will have to be removed for some years in succession; but the author thinks there will be no need for such an extreme measure at Porto Rico. In this case, however, the plant should be kept level with the soil by using the ground two or three years in succession for the production of cut forage. Then, after a light ploughing, some crop should be grown that

requires the use of a cultivator. With a little more effort, by extirpating the plants of *S. halepense* as they emerge from the ground, the work will be crowned with complete success.

## INJURIOUS INSECTS AND OTHER LOWER ANIMALS.

### MEANS OF PREVENTION AND CONTROL

1431 - Enemies of the Chinch-bug (*Blissus leucopterus*), Observed in Illinois, U. S. A. (1).— FLINT, W. P., in the *Journal of Economic Entomology*, Vol. XI, No. 5, pp. 415-419. Concord, N. H., 1918.

Up to now it has usually been supposed that the enemies preying on the chinch-bug were only of very limited efficacy in limiting the ravages of that insect. Observations made in Illinois during the recent plague there of this hemipteron (1909-1915) show the contrary however.

The enemies most commonly found feeding on *Blissus leucopterus* in the infested zone were adults and nymphs of the damsel bug (*Reduviolus ferus*), larvae of *Chrysopa* and *Hemerobius*, adult *Blechnus glabratus* and *Bl. pusio*, nymphs and adults of *Pagasa fusca*, larvae of various species of Coccinellidae, nymphs and adults of the flower bug (*Triphleps insidiosus*).

*Casnomia pennsylvanica* feeds on small numbers of the bug, while *Agonoderus pallipes* eats the dead bugs and their moulted skin.

Ants were never seen to attack the living insect.

Judging from the abundance of enemies in the fields infested by *Blissus leucopterus*, and the numbers of the latter eaten by them it is probable that when, after a period of abundance, the development and spread of the hemipteron are stopped by weather conditions, their enemies, with *Eumicrosoma benefica* (parasite of the eggs of *Blissus*), might even prevent the pest from becoming harmful for some years. Thus, over a large area of Illinois, infested by chinch-bugs, no damage was noted in 1917, which is partly due to the abundance of predatory species in the fields. *Red. ferus* and *Pag. fusca* were extraordinarily abundant in fields infested by *Bl. leucopterus* during the summer of 1918.

1432 - Parasites of *Porthetria dispar* (Gipsy Moth) in Spain (2).—MURCIET, R. G., in the *Revista de Montes*, Year XLII, No. 1004, pp. 775-781 + 2 Figs. Madrid, 1918.

The larvae of the gipsy moth (*Porthetria dispar* L.)—known in some districts in Spain under the name of "lagarta" and very injurious to oaks, whose leaves it eats—are spreading alarmingly in the neighbourhood of Madrid (Casa de Campo, El Pardo and Puerta de Hierro).

However, the macrolepidopteron is not exempt from parasites in Spain. The following chalcids, parasitic on its eggs, are described briefly by the author:—

1) *Anastatus bifasciatus*, very abundant and one of the most efficacious enemies of the gipsy moth;

2) *Schedius kuwanæ*; not less efficient than the preceding one;

(1) See R., June 1914, No. 588; R., July, 1915, No. 768. (Ed.)

(2) See R., May, 1911, No. 1568; R., August-September-October, 1911, No. 3025; R., March, 1916, pp. 330-331. (Ed.)

3) *Atoposomoidea ogimae*, not very abundant. In addition there exists in Spain a new species *Tyndarichus* which might perhaps replace *Tynd. navae* among the chalcids parasitic on the eggs of the gipsy moth.<sup>25</sup>

1433 - *Apanteles lacteicolor* and *Meteorus versicolor*, } Hymenoptera  
Parasitic on the Brown-Tail Moth (*Euproctis chrysorrhea*), Imported into  
the United States from Europe (1). — MUESEBECK, C. F. W., in the *Journal of*  
*Agricultural Research*, Vol. XIV, No. 5, pp. 191-206. Washington, July 29, 1918.

In the winter of 1905-1906, as the result of arrangements made by the Washington Bureau of Entomology for the importation from Europe into New England of parasites of *Porthetria dispar* (gipsy moth or bombyx disparate, spongy, zigzag) and *Euproctis chrysorrhea* (brown-tail moth), a large number of winter webs of the second species were sent from Massachusetts to the special laboratory, then at North Saugus, but moved later to Melrose Highlands. This material was placed in special tubes, and, at the beginning of the following spring, were observed in the tubes numerous specimens of *Pteromalus egregius*, a chalcidoid ectoparasite of the wintering brown-tail moth larvae, as well as many specimens of *Monodontomerus aereus* Walker, another chalcidoid which often hibernates in the adult stage in the web of the moth. The moth larvae soon became active. As it seemed unlikely that these larvae should be the hosts of endoparasites they were removed from the tubes and destroyed with the exception of a few which Mr. E. S. H. TITUS, who was then directing the investigations, continued to feed for a certain time. From these larvae were obtained two braconid parasites, one belonging to the genus *Apanteles*, the other to the genus *Meteorus*.

As the result of the discovery made by Mr. TITUS, the moth larvae in webs received in America during succeeding winters were not destroyed when they emerged in spring, but were fed for several weeks in order to rear out any endoparasites they might contain. This method was followed till 1911, when importation was stopped. There were then available for distribution in localities infested by the brown-tail moth about 40 000 cocoons of *Apanteles lacteicolor* and 1 600 of *Meteorus versicolor*. These species are widely distributed in Europe, both having been obtained from moth webs sent from France, Holland, Germany, Russia (especially South Russia), Austria, Switzerland, and Italy. The spread of the parasites has been so rapid that, although only 150 colonies of *Apanteles* and 20 of *Meteorus* have so far been distributed in 135 and 18 localities respectively, no further colonies are required. Both parasites have been recovered from the whole brown-tail moth area either by rearing the moth larvae in spring or by dissecting the hibernating larvae.

The two braconids which hibernate in the brown-tail moth larvae, *A. lacteicolor* and *M. versicolor*, were first described by VIERECK and WESMAEL in 1911 and 1835 respectively. A more complete description of the adults of both species is now given and their biology discussed in detail.

(1) See R. Aug.-Sept.,-Oct. 1911, No. 3025; R. Nov.-Dec., 1911, No. 3252; R. March, 1916, pp. 330-331. (Ed.)

*A. lacteicolor* is of great importance as a means of control. It is such an efficient parasite that 20 to 25 % of brown-tail moth larvae in a web are often attacked. Its value is increased by the fact that, in America, it has several generations a year and is a more or less important parasite of the gipsy moth and other native injurious species. Moreover, *A. lacteicolor* destroys its hosts in their early stages, preventing them from doing any serious damage by considerably delaying their development. The weak point in the life cycle of *A. lacteicolor* is its evident dependence on the brown-tail moth for hibernation. The moth is now beginning to disappear so that *A. lacteicolor* is becoming gradually less abundant, thus materially reducing its parasitism on *Porth. dispar* and other native hosts.

*M. versicolor* is much inferior to *A. lacteicolor* as a parasite of the hibernating brown-tail moth larvae of which it only destroys a small percentage. On some occasions cocoons of *M. versicolor* have been found in enormous numbers in serious brown-tail moth infestations, but these cases are rare. Moreover, parasitism on the almost full-grown brown-tail moth larvae is slight, and that upon native larvae appears almost insignificant. The slight importance of this parasite as compared with *A. lacteicolor* is probably largely due to its dependence on the brown-tail moth for hibernation, and the fact that it, in its turn, is exposed to attack from various parasites. Another factor reducing the importance of this *Meteorus* is the frequent failure of the larvae to transform to pupae when they have spun cocoons. When *A. lacteicolor* larvae occur in the same hibernating brown-tail moth larvae as *M. versicolor* they cause the death of these latter.

INSECTS, ETC  
INJURIOUS  
TO VARIOUS  
CROPS

1434 - The Control of *Cylas formicarius*, a Coleopteron Attacking Sweet Potatoes, at Porto Rico (1). — SMYTH, E. G., in the *Revista de Agricultura de Puerto Rico*, Vol. I, No. 3, pp. 136-139. San Juan, 1918

At Porto Rico *Cylas formicarius* ("gorgojo de la batata" or "gorgojo de la raíz de la batata"), which has been present in the island for a long time, sometimes destroys more than 75 % of the sweet potato crop and makes it impossible to continue cultivating it. The injury is done by the larva and the adult which hollow galleries in the root, making it unfit for consumption.

When new plantations are formed it is important to be certain that the insect is neither present in the soil nor introduced in the cuttings used. If it be doubtful that the plants from which cuttings are to be made are free from the parasite cuttings must be made from healthy plants which have been previously fumigated with carbon bisulphide and placed in a nursery at a distance from infested plantations.

It is very difficult to free a heavily infested, large sweet potato plantation from the insect. The only method is to harvest all the tubers as soon as the pest is discovered; the longer this is delayed the more difficult will

(1) See R. March, 1911, No. 1058; R. April, 1911, No. 1319; R. Jan., 1916, No. 120; R. Aug., 1918, No. 936 (Ed.)

it be to destroy the insect completely. When harvesting the roots care must be taken to leave no infested ones on the ground or the crop next grown in the same soil will be infected. Potatoes suitable for sale must be immediately removed from the field, and those to be used for propagation fumigated without delay. Attacked tubers which have no market value may be first boiled to kill the adult and larval stages of the insects and then fed to stock. Tubers which are useless even as cattle-food should be burnt or buried deeply, care being taken to leave none of them above soil. All the stems should, at the same time, be heaped up and given to stock, or pigs may be turned into the field till all the stems are eaten. By no means should pigs be turned into the field as soon as the marketable potatoes have been sold. The tubers infested by the insects, which are precisely those which should be destroyed are refused by pigs and, being left on the ground, cause new infestation.

1435 - *Pectinophora gossypiella*, a Microlepidopteron Injurious to Cotton in Egypt (1). — See No. 1356 of this Review.

1436 - Observations on the Coleopteron *Lasioderma serricorne* and the Lepidopteron *Setomorpha margalaestriata*, Injurious to Tobacco, in the Dutch East Indies (2). — KEUCHENIUS, P. E., in the *Mededeelingen van het Besoekisch Proefstation*, No. 26, pp. 1-56 + 1 Plate. 1917.

Publication of the author's work on *Lasioderma serricorne* ("tabaks-boeboek") and *Setomorpha margalaestriata* ("tabaksmot") and the means of controlling them.

*L. serricorne* is attracted to lamp-light, and this property may be used in controlling it; molasses also attracts this insect. In tobacco the adult lives 25 days; the female produces about 30 eggs. About 1 ½ months are required for the insect to become full grown. The incubation of the eggs requires from 4 to 14 days; the larval stage lasts from 30 to 60 days and the pupal stage about 12 days. This *Lasioderma* is omnivorous, it attacks many products, the finest qualities of tobacco being chosen by preference. By placing the insect in a room heated to 60°C. for 20 minutes, all stages of its development are killed. A temperature of about 8°C. for 7 days has the same effect. A temperature of about 0°C. for 5 consecutive days does not kill the eggs, but kills the larvae, pupae and adults. Experiments made with low temperatures have shown that both eggs and larvae of the insect can survive a moderately cold winter.

The following observations regarding *Set. margalaestriata* are given by the author: — This lepidopteron occurs in Java and Sumatra. Besides tobacco it attacks tobacco seeds, clothes, leather and dried coca leaves. The female lays from 100-150 eggs; the life cycle requires from 40-60 days.

(1) See R., Nov. 1918, No. 1309.

(2) See R., Nov. 1914, No. 1081; R. May 1916, No. 590; R. June 1916, No. 711; R. Dec. 1917, No. 1261. (Ed.)

The egg hatches in from 7 to 8 days, the larval stage lasts from 3 to 5 weeks and the pupal stage 14 days. A temperature of 42°C for 5 hours kills the insect in all its stages; a temperature of 0°C. for 5 days has the same effect. It may thus be concluded that the insect could not survive the winter in a temperate region. The author mentions a few means of control and discusses the results obtained with them. As measures to take for avoiding infection all the tobacco barns should be paved with concrete, the barns should be disinfected and all the tobacco or other products liable to attack and intended for export should be fumigated with carbon bisulphide. The disinfection should take place 5 days before embarking, so that the carbon bisulphide can escape completely. The Dock and Shipping Companies must be forbidden to place disinfected goods along by infected goods. Tobacco destined to the Colonies should be disinfected in Holland and in the other exporting countries.

1437 - *Clytus devastator*, a Coleopteron Injurious to Citrus and Other Plants, in Cuba and Florida. — BACK, E. A., in the *Journal of Economic Entomology*, Vol. XI, No. 5, pp. 411-414 + Plate. Concord, N. H., 1918.

The cerambycid beetle *Clytus devastator*, first described in 1836 by DELAPORTE DE CASTELNAU and GORY as a serious pest of lemons in Cuba, has, of recent years, been also reported from Florida as a pest of citrus and other plants. In Cuba, specimens of the insect have been bred out at Cayamas in 1910 from Cuban mahogany while other specimens have been taken at Central Constancia. The beetle has been observed in the following localities between 1903 to 1910: — Palm Beach, Key West, Paradise Key, Chase and Perico Island, near Anna Maria Key at the entry to Pampa bay. The specimens from Chase were bred out from the pomegranate tree; that of Paradise Key was taken flying. Although at first recorded as a dangerous pest of *Citrus* in Cuba, the insect was only bred out from *Citrus* in the spring of 1910 in Perico Island, when its larvae caused serious damage to the orange trees by hollowing out galleries in the trunk and branches. According to E. A. SCHWARZ its favourite host is *Rhizophora Mangle*.

The author calls attention to this beetle which might seriously harm the Florida citrus trade.

1438 - Pests of Stored Food-stuff, in Java. — KEUCHENIUS P. B., in *Teymannia*, Year XXIX, Pt. 4, pp. 216-221 Batavia, 1915.

The author has drawn up a list of the pests recorded in the foodstuffs stored in Eastern Java: — *Lasioderma serricorne*, *Scotomorpha marginalae-striata*, *Araucocerus fasciculatus*, *Rhizophorha dominica*, *Tenebrioides mauritanicus*, *Silvanus surinamensis*, *Calandra oryzae*, *Tribolium castaneum*, *Gonocephalum hoffmannseggii*, *Thaneroclerus buquet*, *Necrobia rufipes*, *Laeophloeus* sp., *Carpophilus* spp., *Thagora figurana*, etc.

Many of these pests are not very specialised in their choice of food as the same species can often be found in different foodstuffs. Although some species are not always directly injurious to the product — some of them may even be useful, e. g., *Necrobia rufipes* and *Thaneroclerus buquet* which

drive out all the other pests present in the product — they always reduce its value.

The author discusses methods of disinfection. Treatment with steam or low temperatures is always expensive in the East Indies; X rays can only be used where electric current is cheap; carbon tetrachloride is less advisable than carbon bisulphide on account of its price; prussic acid gas, so very poisonous, can only be used for disinfecting loose products; the disadvantages of this gas are: — the great danger it presents to those applying it, the special glass generators required for preparing it, the rapid loss of its toxicity as it is so easily absorbed by the water contained in the products; sulphur dioxide which besides not having a very strong action, has a bad effect on many products (tobacco, cacao, flour, etc.).

In many cases, a high temperature can be used for disinfection especially if the plantation has a drier. If this last method cannot be used, treatment with carbon bisulphide is advisable. This has so far given the best results and has no effect on the quality of the following products: — hybrid coffee, cacao, tobacco, groundnuts, flour, copra, maize, rice and coca; it produces an insignificant change of shade in the berries of *Coffea robusta*. To disinfect a cubic metre in 24 hours 185 cc. are required, and for the same volume in 48 hours 100 cc. suffices, and in 72 hours 80 cc. The method consists in placing the material to be disinfected into a hermetically closed space in which, at the height of the ceiling, saucers containing carbon bisulphide are placed.

[1438]
